(54) Title: COMPUTER-BASED TOOL AND METHOD FOR DESIGNING AN ELECTRONIC CIRCUIT AND RELATED SYSTEM AND LIBRARY FOR SAME

(57) Abstract: A computer-based circuit-design tool includes a front end, an interpreter coupled to the front end, and a generator coupled the interpreter. The front end receives symbols that define an algorithm, and the interpreter parses the algorithm into respective algorithm portions. The generator identifies a corresponding circuit template for each of the algorithm portions, each template defining a circuit for executing the respective algorithm portion, and interconnects the identified templates such that the interconnected templates define a circuit that is operable to execute the algorithm. As compared to prior design tools, this tool may decrease the time and effort required to design a circuit for instantiation on a programmable logic integrated circuit (PLIC) or on an application-specific integrated circuit (ASIC) by allowing one to construct the circuit from previously written templates that define previously tested and debugged circuits. A library includes one or more circuit templates and an interface template. The one or more circuit templates each define a respective circuit operable to execute a respective algorithm or portion thereof. And the interface template defines a hardware layer operable to interface one of the circuits to pins of a programmable logic circuit when the layer and the one circuit are instantiated on the programmable logic circuit. Such a library may shorten the time and reduce the effort that an engineer expends designing a circuit for instantiation on a PLIC or ASIC by allowing the engineer to build the circuit from templates of previously designed and debugged circuits.

WO 2006/039710 A2

COMPUTER-BASED TOOL AND METHOD FOR DESIGNING AN ELECTRONIC CIRCUIT AND RELATED SYSTEM AND LIBRARY FOR SAME

CLAIM OF PRIORITY

[1] This application claims priority to U.S. Provisional Application Serial Nos. 60/615,192, 60/615,157, 60/615,170, 60/615,158, 60/615,193, and 60/615,050, filed on 01 October 2004, which are incorporated by reference.

CROSS REFERENCE TO RELATED APPLICATIONS

[2] This application is related to U.S. Patent Application Serial Nos. _____ (Attorney Docket Nos. 1934-021-03, 1934-024-03, 1934-025-03, 1934-026-03, 1934-031-03, 1934-035-03, and 1934-036-03), which have a common filing date of 03 October 2005 and assignee and which are incorporated by reference.

BACKGROUND

[3] Electronics engineers often instantiate circuits, such as logic circuits, on programmable logic integrated circuits (PLICs) such as field-programmable gate arrays (FPGAs), and on application-specific integrated circuits (ASICs). Because an engineer typically configures with firmware the circuit components and interconnections inside of a PLIC, he can modify a circuit instantiated on the PLIC merely by modifying and reloading the firmware. An example of a computer architecture that exploits the ability to configure and reconfigure circuitry within a PLIC with firmware is described in U.S. Patent Publication No. 2004/0133763, which is incorporated herein by reference.

[4] But unfortunately, it is often difficult and time consuming to design a circuit for instantiation on a PLIC, and an increase in the level of design difficulty and the time required to complete the design often

accompany the routing resources, component density, and component variety on a PLIC.

[5] Comparatively, when a software programmer writes source code for a software application, he can often save time by incorporating into the application previously written and debugged software objects from a software-object library. Suppose the programmer wishes to write a software application that solves for *y* in the following equation:

$$(1) \quad y = x^2 + z^3$$

Further suppose that a software-object library includes a first software object for squaring a value (here *x*), a second software object for cubing a value (here *z*), and a third software object for summing two values (here x^2 and z^3). By incorporating pointers to these three objects in the source code, a compiler effectively merges these objects into the software application while compiling the source code. Therefore, the object library allows the programmer to write the software application in a shorter time and with less effort because the programmer does not have to "reinvent the wheel" by writing and debugging pieces of source code that respectively square *x*, cube *z*, and sum x^2 and z^3. Furthermore, if the programmer needs to modify the software application, he can do so without modifying and re-debugging the first, second, and third software objects.

[6] In contrast, there are typically no time- or effort-saving equivalents of software objects available to a hardware engineer who wishes to design a circuit for instantiation on a PLIC; consequently, when a hardware engineer designs a circuit for instantiation on a PLIC, he typically must write the source code (*e.g.*, Verilog Hardware Description Language (VHDL)) "from scratch." Suppose that an engineer wishes to design a logic circuit that solves for *y* equation (1). Because there are typically no

hardware equivalents of the first, second, and third software objects described in the preceding paragraph, the engineer may write source code that describes first and second portions of a circuit for solving equation (1). The first circuit portion squares x, cubes z, and sums x^2 and z^3, and the second circuit portion interfaces the first circuit portion to the external pins of the PLIC. The engineer then compiles the source code with PLIC design tool (typically provided by the PLIC manufacturer), which synthesizes and routes the circuit and then generates the configuration firmware that, when loaded into the PLIC, instantiates the circuit. Next, the engineer loads the firmware into the PLIC and debugs the instantiated circuit. Unfortunately, the synthesizing and routing steps are often not trivial, and may take a number of hours or even days depending upon the size and complexity of the circuit. And even if the engineer makes only a minor modification to a small portion of the circuit, he typically must repeat the synthesizing, routing, and debugging steps for the entire circuit.

[7] Another factor that may add to the time and effort that an engineer expends while designing a circuit for instantiation on a PLIC is that a PLIC design tool typically recognizes only hardware-specific source code. Suppose that a mathematician, who writes an equation using mathematical symbols (*e.g.*, "+," "-," "≤," "∑," "∫," "∂," "x^2," "z^3," and "√"), wishes to instantiate on a PLIC a circuit that solves for a variable in a complex equation that includes, *e.g.*, partial derivatives and integrations. Because a PLIC design tool typically recognizes few, if any, mathematical symbols, the mathematician often must explain the equation and the desired operating parameters (*e.g.*, latency and precision) of the circuit to a hardware engineer, who then translates the equation and operating parameters into source code that the design tool recognizes. These explanation and translation steps are often time consuming and difficult for the engineer, particularly where the equation is mathematically complex or the circuit has stringent operating parameters (*e.g.*, high speed, high precision).

[8] Therefore, a need has arisen for a new methodology and for a new tool for designing a circuit for instantiation on a PLIC.

SUMMARY

[9] According to an embodiment of the invention, a computer-based circuit design tool includes a front end, an interpreter coupled to the front end, and an integrator coupled to the interpreter. The front end receives symbols that define a logical expression, and the interpreter parses the expression into respective portions. The integrator identifies a corresponding circuit template for each of the expression portions, and logically interconnects the identified templates into a representation of an electronic circuit that is operable to execute the expression.

[10] As compared to prior circuit design tools, such a tool may shorten the time and reduce the effort that an engineer expends designing a circuit for instantiation on a PLIC by allowing the engineer to build the circuit from templates of previously designed and debugged circuits.

[11] According to a related embodiment of the invention, the front end of the design tool recognizes mathematical symbols so that one can design a PLIC circuit for executing a mathematical expression with little or no assistance from a hardware engineer.

[12] According to an embodiment of the invention, a library includes one or more circuit templates and an interface template. The one or more circuit templates each define a respective circuit operable to execute a respective algorithm or portion thereof. And the interface template defines a hardware layer operable to interface one of the circuits to pins of a programmable logic circuit when the layer and the one circuit are instantiated on the programmable logic circuit.

[13] Such a library may shorten the time and reduce the effort that an engineer expends designing a circuit for instantiation on a PLIC or ASIC

by allowing the engineer to build the circuit from templates of previously designed and debugged circuits.

Brief Description of the Drawings

[14] **FIG. 1** is a block diagram of a peer-vector computing machine having a pipelined accelerator that one can design with a design tool according to an embodiment of the invention.

[15] **FIG. 2** is a block diagram of a pipeline unit that includes a PLIC and that can be included in the pipelined accelerator of **FIG. 1** according to an embodiment of the invention.

[16] **FIG. 3** is a diagram of the circuit layers that compose the hardware interface layer within the PLIC of **FIG. 2** according to an embodiment of the invention.

[17] **FIG. 4** is a block diagram of the circuitry that composes the interface adapter and framework services layers of **FIG. 3** according to an embodiment of the invention.

[18] **FIG. 5** is a diagram of a hardware-description file for a circuit that one can instantiate on a PLIC according to an embodiment of the invention.

[19] **FIG. 6** is a block diagram of a PLIC circuit-template library according to an embodiment of the invention.

[20] **FIG. 7** is a block diagram of circuit-design system that includes a computer-based tool for designing a circuit using templates from the library of **FIG. 6** according to an embodiment of the invention.

[21] **FIG. 8** illustrates the parsing of a mathematical expression according to an embodiment of the invention.

[22] **FIG. 9** illustrates a table of hardwired-pipeline library templates corresponding to the hardwired-pipelines available for executing respective

portions of the parsed mathematical expression of **FIG. 8** according to an embodiment of the invention.

[23] **FIG. 10** is a block diagram of a circuit that the tool of **FIG. 7** generates from circuit templates downloaded from the library of **FIG. 6** according to an embodiment of the invention.

[24] **FIG. 11** is a block diagram of a circuit that the tool of **FIG. 7** generates from circuit templates downloaded from the library of **FIG. 6** according to another embodiment of the invention.

[25] **FIG. 12** is a block diagram of a circuit that the tool of **FIG. 7** generates from circuit templates downloaded from the library of **FIG. 6** according to yet another embodiment of the invention.

[26] **FIG. 13** is a block diagram of a circuit that the tool of **FIG. 7** generates for implementing a function as a series expansion according to an embodiment of the invention.

[27] **FIG. 14** is a block diagram of a circuit that the tool of **FIG. 7** generates for implementing the function of **FIG. 13** as a series expansion according to another embodiment of the invention.

[28] **FIG. 15** is a block diagram of a power-of-x term generator that the tool of **FIG. 7** generates as a replacement for the power-of-x multipliers of **FIGS. 13** and **14** according to an embodiment of the invention.

[29] **FIG. 16** is a block diagram of a circuit that the tool of **FIG. 7** generates for implementing another function as a series expansion according to an embodiment of the invention.

[30] **FIG. 17** is a block diagram of a sign determiner from **FIG. 16** according to an embodiment of the invention.

DETAILED DESCRIPTION

Introduction

[31] A computer-based circuit design tool according to an embodiment of the invention is discussed below in conjunction with **FIGS. 7 – 10**.

[32] But first is presented in conjunction with **FIGS. 1 – 6** an overview of concepts that are related to the design tool according to an embodiment of the invention. An understanding of these concepts should facilitate the reader's understanding of the design tool.

Overview Of Concepts Related To Design Tool

[33] **FIG. 1** is a schematic block diagram of a computing machine ***10***, which has a peer-vector architecture according to an embodiment of the invention. In addition to a host processor ***12***, the peer-vector machine ***10*** includes a pipelined accelerator ***14***, which is operable to process at least a portion of the data processed by the machine ***10***. Therefore, the host-processor ***12*** and the accelerator ***14*** are "peers" that can transfer data messages back and forth. Because the accelerator ***14*** includes hardwired logic circuits instantiated on one or more PLICs, it executes few, if any, program instructions, and thus typically performs mathematically intensive operations on data significantly faster than a bank of computer processors can for a given clock frequency. Consequently, by combing the decision-making ability of the processor ***12*** and the number-crunching ability of the accelerator ***14***, the machine ***10*** has the same abilities as, but can often process data faster than, a conventional processor-based computing machine. Furthermore, as discussed below and in U.S. Patent Publication No. 2004/0136241, which is incorporated by reference, providing the accelerator ***14*** with a communication interface that is compatible with the interface of the host processor ***12*** facilitates the design and modification of the machine ***10***, particularly where the communication interface is an industry standard. And where the accelerator ***14*** includes multiple pipeline units (**FIG. 2**), providing each of these units with this compatible communication interface facilitates the design and modification

of the accelerator, particularly where the communication interface is an industry standard. Moreover, the machine ***10*** may also provide other advantages as described in the following other patent publications, which are incorporated by reference: 2004/0133763; 2004/0181621; 2004/0170070; and, 2004/0130927.

[34] Still referring to **FIG. 1**, in addition to the host processor ***12*** and the pipelined accelerator ***14***, the peer-vector computing machine ***10*** includes a processor memory ***16***, an interface memory ***18***, a bus ***20***, a firmware memory ***22***, an optional raw-data input port ***24***, an optional processed-data output port ***26***, and an optional router ***31***.

[35] The host processor ***12*** includes a processing unit ***32*** and a message handler ***34***, and the processor memory ***16*** includes a processing-unit memory ***36*** and a handler memory ***38***, which respectively serve as both program and working memories for the processor unit and the message handler. The processor memory ***36*** also includes an accelerator-configuration registry ***40*** and a message-configuration registry ***42***, which store respective configuration data that allow the host processor ***12*** to configure the functioning of the accelerator ***14*** and the structure of the messages that the message handler ***34*** sends and receives.

[36] The pipelined accelerator ***14*** includes at least one PLIC (**FIG. 2**) on which are disposed hardwired pipeline $44_1 - 44_n$, which process respective data while executing few, if any, program instructions. The firmware memory ***22*** stores the configuration firmware for the PLIC(s) of the accelerator ***14***. If the accelerator ***14*** is disposed on multiple PLICs, these PLICs and their respective firmware memories may be disposed on multiple circuit boards that are often called daughter cards or pipeline units (**FIG. 2**). The accelerator ***14*** and pipeline units are discussed further in previously incorporated U.S. Patent Publication Nos. 2004/0136241, 2004/0181621,

and 2004/0130927. The pipeline units are also discussed below in conjunction with **FIGS. 2 – 4**.

[37] Generally, in one mode of operation of the peer-vector computing machine ***10***, the pipelined accelerator ***14*** receives data from one or more software applications running on the host processor ***12***, processes this data in a pipelined fashion with one or more logic circuits that execute one or more mathematical algorithms, and then returns the resulting data to the application(s). As stated above, because the logic circuits execute few if any software instructions, they often process data one or more orders of magnitude faster than the host processor ***12***. Furthermore, because the logic circuits are instantiated on one or more PLICs, one can modify these circuits merely by modifying the firmware stored in the memory ***52***; that is, one need not modify the hardware components of the accelerator ***14*** or the interconnections between these components. The operation of the peer-vector machine ***10*** is further discussed in previously incorporated U.S. Patent Publication No. 2004/0133763, the functional topology and operation of the host processor ***12*** is further discussed in previously incorporated U.S. Patent Publication No. 2004/0181621, and the topology and operation of the accelerator ***14*** is further discussed in previously incorporated U.S. Patent Publication No. 2004/0136241.

[38] **FIG. 2** is a diagram of a pipeline unit ***50*** of the pipelined accelerator ***14*** of **FIG. 1** according to an embodiment of the invention.

[39] The unit ***50*** includes a circuit board ***52*** on which are disposed the firmware memory ***22***, a platform-identification memory ***54***, a bus connector ***56***, a data memory ***58***, and a PLIC ***60***.

[40] As discussed above in conjunction with **FIG. 1**, the firmware memory ***22*** stores the configuration firmware that the PLIC ***60*** downloads to instantiate one or more logic circuits.

[41] The platform memory ***54*** stores a value that identifies the one or more platforms with which the pipeline unit ***50*** is compatible. Generally, a platform specifies a unique set of physical attributes that a pipeline unit may possess. Examples of these attributes include the number of external pins (not shown) on the PLIC ***60***, the width of the bus connector ***56***, the size of the PLIC, and the size of the data memory. Consequently, a pipeline unit ***50*** is compatible with a platform if the unit possesses all of the attributes that the platform specifies. So a pipeline unit ***50*** having a bus connector ***56*** with thirty-two bits is incompatible with a platform that specifies a bus connector with sixty-four bits. Some platforms may be compatible with the peer vector machine ***10*** (**FIG. 1**), and others may be incompatible. Therefore, the platform identifier stored in the memory ***54*** may allow the host processor ***12*** (**FIG. 1**) to determine whether the pipeline unit ***50*** is compatible with the platforms supported by the machine ***10***. And where the pipeline unit ***50*** is so compatible, the platform identifier may also allow the host processor ***12*** to determine how to configure the PLIC ***60*** or other portions of the pipeline unit.

[42] The bus connector ***56*** is a physical connector that interfaces the PLIC ***60***, and perhaps other components of the pipeline unit ***50***, with the pipeline bus ***20*** of **FIG. 1**.

[43] The data memory ***58*** acts as a buffer for storing data that the pipeline unit ***50*** receives from the host processor ***12*** (**FIG. 1**) and for providing this data to the PLIC ***60***. The data memory ***58*** may also act as a buffer for storing data that the PLIC ***60*** generates for sending to the host processor ***12***, or as a working memory for the hardwired pipelines ***44***.

[44] Instantiated on the PLIC ***60*** are logic circuits that compose the hardwired pipeline(s) ***44*** and a hardware interface layer ***62***, which interfaces the hardwired pipelines to the external pins (not shown) of the PLIC ***60***, and which thus interfaces the pipelines to the pipeline bus ***20*** (via the connector ***56***), the firmware and platform-identification memories ***22*** and ***54***, and the

data memory ***58***. Because the topology of interface layer ***62*** is primarily dependent upon the attributes specified by the platform(s) with which the pipeline unit ***50*** is compatible, one can often modify the pipeline(s) ***44*** without modifying the interface layer. For example, if a platform with which the pipeline unit ***50*** is compatible specifies a thirty-two-bit bus, then the interface layer ***62*** provides a thirty-two-bit bus connection to the bus connector ***60*** regardless of the topology or other attributes of the pipeline(s) ***44***. Consequently, as discussed below in conjunction with **FIGS. 7 – 10**, an embodiment of the computer-based design tool allows one to design and debug the pipeline(s) ***44*** independently of the interface layer ***62***, and vice versa.

[45] Still referring to **FIG. 2**, alternate embodiments of the pipeline unit ***50*** are contemplated. For example, the memory ***54*** may be omitted, and the platform identifier may stored in the firmware memory **22**, or by a jumper-configurable or hardwired circuit (not shown).

[46] A pipeline unit similar to the unit ***50*** is discussed in previously incorporated U.S. Patent Publication No. 2004/0136241.

[47] **FIG. 3** is a diagram of the hardware layers that compose the hardware interface layer ***62*** within the PLIC ***60*** of **FIG. 2** according to an embodiment of the invention. The hardware interface layer ***62*** includes three layers of circuitry that is instantiated on the PLIC ***60***: an interface-adapter layer ***70***, a framework-services layer ***72***, and a communication layer ***74***, which is hereinafter called a communication shell. The interface-adapter layer ***70*** includes circuitry, *e.g.*, buffers and latches, that interfaces the framework-services layer ***72*** to the external pins (not shown) of the PLIC ***60***. The framework-services layer ***72*** provides a set of services to the hardwired pipeline(s) ***44*** via the communication shell ***74***. For example, the layer ***72*** may synchronize data transfer between the pipeline(s) ***44***, the pipeline bus ***20*** (**FIG. 1**), and the data memory ***58*** (**FIG. 2**), and may control the sequence(s) in which the pipeline(s) operate. The

communication shell ***74*** includes circuitry, *e.g.*, latches, that interface the framework-services layer ***72*** to the pipeline(s) ***44***.

[48] Still referring to **FIG. 3**, alternate embodiments of the hardware-interface layer ***62*** are contemplated. For example, although the framework-services layer ***72*** is shown as isolating the interface-adapter layer ***70*** from the communication shell ***74***, the interface-adapter layer may, at least at some circuit nodes, be directly coupled to the communication shell. Furthermore, although the communication shell ***74*** is shown as isolating the interface-adapter layer ***70*** and the framework-services layer ***72*** from the hardwired pipeline(s) ***44***, the interface-adapter layer or the framework-services layer may, at least at some circuit nodes, be directly coupled to the pipeline(s).

[49] **FIG. 4** is a schematic block diagram of the circuitry that composes the interface-adapter layer ***70*** and the framework-services layer ***72*** of **FIG. 3** according to an embodiment of the invention.

[50] A communication interface ***80*** and an optional industry-standard bus interface ***82*** compose the interface-adapter layer ***70***, and a controller ***84***, exception manager ***86***, and configuration manager ***88*** compose the framework-services layer ***72***.

[51] The communication interface ***80*** transfers data between a peer, such as the host processor ***12*** (**FIG. 1**) or another pipeline unit ***50*** (**FIG. 2**), and the firmware memory ***22***, the platform-identifier memory ***54***, the data memory ***58***, and the following components instantiated within the PLIC ***60***: the hardwired pipelines ***44*** (via the communication shell ***74***), the controller ***86***, the exception manager ***88***, and the configuration manager ***90***. If present, the optional industry-standard bus interface ***82*** couples the communication interface ***80*** to the bus connector ***56***. Alternatively, the interfaces ***80*** and ***82*** may be combined such that the functionality of the interface ***82*** is included within the communication interface ***80***.

[52] The controller ***84*** synchronizes the hardwired pipelines ***44$_1$*** – ***44$_n$*** and monitors and controls the sequence in which they perform the respective data operations in response to communications, *i.e.*, "events," from other peers. For example, a peer such as the host processor ***12*** may send an event to the pipeline unit ***50*** via the pipeline bus ***20*** to indicate that the peer has finished sending a block of data to the pipeline unit and to cause the hardwired pipelines ***44$_1$*** – ***44$_n$*** to begin processing this data. An event that includes data is typically called a message, and an event that does not include data is typically called a "door bell."

[53] The exception manager ***86*** monitors the status of the hardwired pipelines ***44$_1$*** – ***44$_n$***, the communication interface ***80***, the communication shell ***74***, the controller ***84***, and the bus interface ***82*** (if present), and reports exceptions to the host processor ***12*** (**FIG. 1**). For example, if a buffer (not shown) in the communication interface ***80*** overflows, then the exception manager ***86*** reports this to the host processor ***12***. The exception manager may also correct, or attempt to correct, the problem giving rise to the exception. For example, for an overflowing buffer, the exception manager ***86*** may increase the size of the buffer, either directly or via the configuration manager ***88*** as discussed below.

[54] The configuration manager ***88*** sets the "soft" configuration of the hardwired pipelines ***44$_1$*** – ***44$_n$***, the communication interface ***80***, the communication shell ***74***, the controller ***84***, the exception manager ***86***, and the interface ***82*** (if present) in response to soft-configuration data from the host processor ***12*** (**FIG. 1**). As discussed in previously incorporated U.S. Patent Publication No. 2004/0133763, the "hard" configuration of a component within the PLIC ***60*** denotes the actual instantiation, on the transistor and circuit-block level, of the component, and the soft configuration denotes the physical parameters (*e.g.*, data width, table size) of the instantiated component. That is, soft-configuration data is similar to the data that one can load into a register of a processor (not shown in **FIG.**

4) to set the operating mode (*e.g.*, burst-memory mode) of the processor. For example, the host processor ***12*** may send to the PLIC ***60*** soft-configuration data that causes the configuration manager ***88*** to set the number and respective priority levels of queues (not shown) within the communication interface ***80***. The exception manager ***86*** may also send soft-configuration data that causes the configuration manager ***88*** to, *e.g.*, increase the size of an overflowing buffer in the communication interface ***80***.

[55] The communication interface ***80***, optional industry-standard bus interface ***82***, controller ***84***, exception manager ***86***, and configuration manager ***88*** are further discussed in previously incorporated U.S. Patent Publication No. 2004/0136241.

[56] Referring again to **FIG. 2**, although the pipeline unit ***50*** is disclosed as including only one PLIC ***60***, the pipeline unit may include multiple PLICs. For example, as discussed in previously incorporated U.S. Patent Publication No. 2004/0136241, the pipeline unit ***50*** may include two interconnected PLICs, where the circuitry that composes the interface-adapter layer ***70*** and framework-services layer ***72*** is instantiated on one of the PLICs, and the circuitry that composes the communication shell ***74*** and the hardwired pipelines ***44*** is instantiated on the other PLIC.

[57] **FIG. 5** is a diagram of a hardware-description file ***100*** from which a conventional PLIC synthesizer and router tool (not shown) can generate the configuration firmware for the PLIC ***60*** of **FIGS. 2 – 4** according to an embodiment of the invention. Typically, the hardware-description file ***100*** includes templates that are written in a conventional hardware description language (HDL) such as Verilog® HDL. The top-down structure of the file ***100*** resembles the top-down structure of software source code that incorporates software objects. Such a top-down structure for software source code provides at least two advantages. First, it allows a programmer to avoid writing and debugging source code for a

function when a software object that performs the function has already been written and debugged. Second, it allows the programmer to change or add a function by modifying an existing object or writing a new object with little or no rewriting and debugging of the source code that incorporates the object. As discussed below, the top-down structure of the file ***100*** provides similar advantages. For example, it allows one to incorporate in the file ***100*** existing templates that define an already-debugged hardware-interface layer ***62*** (**FIGS. 2 – 3**). Furthermore, it allows one to change an existing hardwired pipeline ***44*** or to add to a circuit a new hardwired pipeline ***44*** with little or no rewriting and debugging of the templates that define the layer ***62***.

[58] The hardware-description file ***100*** includes a top-level template ***101***, which includes respective top-level definitions ***102***, ***104***, and ***106*** of the interface-adapter layer ***70***, the framework-services layer ***72***, and the communication shell ***74*** (collectively the hardware-interface layer ***62***) of the PLIC ***60*** (**FIGS. 2 – 4**). The template ***101*** also defines the connections between the external pins (not shown) of the PLIC ***60*** and the interface-adapter ***70*** (and in some cases the framework-services layer ***72***), and also defines the connections between the framework-services layer (and in some cases the interface-adapter layer) and the communication shell ***74***.

[59] The top-level definition ***102*** of the interface-adapter layer ***70*** (**FIGS. 3 – 4**) incorporates an interface-adapter-layer template ***108***, which further defines the portions of the interface-adapter layer defined by the top-level definition ***102***. For example, suppose that the top-level definition ***102*** defines a data-input buffer (not shown) in terms of its input and output nodes. That is, suppose the top-level definition ***102*** defines the data-input buffer as a functional block having defined input and output nodes. The template ***108*** defines the circuitry that composes this functional buffer block, and defines the connections between this circuitry and the buffer input nodes and output nodes recited in the top-level definition ***102***. Furthermore, the template ***108*** may incorporate one or more lower-level

templates ***109*** that further define the data buffer or other components of the interface-adapter layer ***70*** recited in the template ***108***. Moreover, these one or more lower-level templates ***109*** may each incorporate one or more even lower-level templates (not shown), and so on, until all portions of the interface-adapter layer ***70*** are defined in terms of circuit components (*e.g.*, flip-flops, logic gates) that the PLIC synthesizing and routing tool (not shown) recognizes.

[60] Similarly, the top-level definition ***104*** of the framework-services layer ***72*** (**FIGS. 3 – 4**) incorporates a framework-services-layer template ***110***, which further defines the portions of the framework-services layer defined by the definition ***104***. For example, suppose the top-level definition ***104*** defines a counter (not shown) in terms of its input and output nodes. The template ***110*** defines the circuitry that composes this counter, and defines the connections between this circuitry and the counter input and output nodes recited by the top-level definition ***104***. Furthermore, the template ***110*** may incorporate a hierarchy of one or more lower-level templates ***111*** and even lower-level templates (not shown), and so on, such that all portions of the framework-services layer ***72*** are, at some level of the hierarchy, defined in terms of circuit components (*e.g.*, flip-flops, logic gates) that the PLIC synthesizing and routing tool recognizes. For example, suppose the template ***110*** defines the counter as including a count-up/down-selector circuit having input and output nodes. The template ***110*** may incorporate a lower-level template ***111*** that defines the circuitry within the selector circuit and defines the connections between this circuitry and the selector circuit's input and output nodes defined by the template ***110***.

[61] Likewise, the top-level definition ***106*** of the communication shell ***74*** (**FIGS. 3 – 4**) incorporates a communication-shell template ***112***, which further defines the portions of the communication shell defined by the definition ***106*** and which also includes a top-level definition ***113*** of the

hardwired pipeline(s) ***44*** disposed within the communication shell. For example, the definition ***113*** defines the connections between the communication shell ***74*** and the hardwired pipeline(s) ***44***.

[62] The top-level definition ***113*** of the hardwired pipeline(s) ***44*** (**FIGS. 3 - 4**) incorporates one or more hardwired-pipeline templates ***114***, which further define the portions of the hardwired pipeline(s) ***44*** defined by the definition ***113***. The template or templates ***114*** may each incorporate a hierarchy of one or more lower-level templates ***115*** and even lower-level templates (not shown) such that all portions of the respective pipeline(s) ***44*** are, at some level of the hierarchy, defined in terms of circuit components (*e.g.*, flip-flops, logic gates) that the PLIC synthesizing and routing tool recognizes.

[63] Moreover, the communication-shell template ***112*** may incorporate a hierarchy of one or more lower-level templates ***116*** and even lower-level templates (not shown) such that all portions of the communication shell ***74*** other than the hardwired pipeline(s) ***44*** are, at some level of the hierarchy, defined in terms of circuit components (*e.g.*, flip-flops, logic gates) that the PLIC synthesizing and routing tool recognizes.

[64] Still referring to **FIG. 5**, a configuration template ***118*** provides definitions for one or more parameters having values that one can set to configure the circuitry that the templates ***101***, ***108***, ***110***, ***112***, ***114*** and lower-level templates ***109***, ***111***, ***115***, and ***116*** define. For example, suppose that the bus interface ***82*** of the interface-adapter layer ***70*** (**FIG. 4**) is configurable to have either a thirty-two-bit or a sixty-four-bit interface with the bus connector ***56***. The configuration template ***118*** defines a template BUS-WIDTH, the value of which determines the width of the interface between the interface ***82*** and the connector ***56***. For example, BUS-WIDTH=0 configures the interface ***82*** to have a thirty-two-bit interface, and BUS-WIDTH=1 configures the interface ***82*** to have a sixty-four-bit

interface. Examples of other parameters that may be configurable include the depth of a first-in-first-out (FIFO) data buffer (not shown) disposed within the framework-services layer ***72*** (**FIGS. 2 – 4**), the lengths of messages received and transmitted by the interface-adapter layer ***70***, and the precision and data structure (*e.g.*, integer, floating-point) of the hardwired pipeline(s) ***44***.

[65] One or more of the templates ***101***, ***108***, ***110***, ***112***, ***114*** and the lower-level templates (not shown) incorporate the parameters defined in the configuration template ***118***. The PLIC synthesizer and router tool (not shown) configures the interface-adapter layer ***70***, the framework-services layer ***72***, the communication shell ***74***, and the hardwired pipeline(s) ***44*** (**FIGS. 3 – 4**) according to the values in the template ***118*** during the synthesis of this circuitry. Consequently, to reconfigure the circuit parameters represented by the parameters in the configuration template ***118***, one need only modify the values of these parameters in the template ***118***, and then rerun the synthesizer and router tool on the file ***100***. Alternatively, if one or more of the parameters in the configuration template ***118*** can be sent to the PLIC as soft-configuration data after instantiation of the circuit, then one can modify the corresponding circuit parameters by merely modifying the soft-configuration data. Therefore, according to this alternative, may avoid rerunning the synthesizer and router tool on the file ***100***. Moreover, templates (*e.g.*, ***101***, ***108***, ***109***, ***110***, ***111***, ***112***, ***114***, ***115***, and ***116***) that do not incorporate settable parameters such as those provided by the configuration template ***118*** are sometimes called modules or entities, and are typically lower-level templates that include Boolean expressions that a synthesizer and router tool (not shown) converts into circuitry for implementing the expressions.

[66] Alternate embodiments of the hardware-description file ***100*** are contemplated. For example, although described as defining circuitry for

instantiation on a PLIC, the file ***100*** may define circuitry for instantiation on an ASIC.

[67] **FIG. 6** is a block diagram of a library ***120*** that stores PLIC circuit templates, such as the templates ***101***, ***108***, ***110***, ***112***, and ***114*** (and any existing lower-level templates) of **FIG. 5**, according to an embodiment of the invention.

[68] The library ***120*** has m+1 sections: m sections $122_1 - 122_m$ for the respective m platforms that the library supports, and a section ***124*** for the hardwired-pipelines ***44*** (**FIGS. 2 – 4**) that the library supports.

[69] For example purposes, the library section 122_1 is discussed in detail, it being understood that the other library sections $122_2 - 122_m$ are similar.

[70] The library section 122_1 includes a top-level template 101_1, which is similar in structure to the template ***101*** of **FIG. 5**, and which thus includes top-level definitions 102_1, 104_1, and 106_1 of versions of the interface-adapter layer ***70***, the framework-services layer ***72***, and the communication shell ***74*** that are compatible with the platform m=1.

[71] In this embodiment, we assume that there is only one version of the interface-adapter layer ***70*** and one version of the framework-services layer ***72*** available for each platform m, and, therefore, that the library section 122_1 includes only one interface-adapter-layer template 108_1 and only one framework-services-layer template 110_1. But in an embodiment that includes multiple versions of the interface-adapter layer ***70*** and multiple versions of the framework-services layer ***72*** for each platform m, the library section 122_1 would include multiple interface-adapter- and framework-services-layer templates ***108*** and ***110***.

[72] The library section 122_1 also includes n communication-shell templates $112_{1,1} - 112_{1,n}$, which respectively correspond to the hardwired-pipeline templates $114_1 - 114_n$ in the library section ***124***. As

stated above in conjunction with **FIG. 3**, the communication shell ***74*** interfaces a hardwired pipeline or hardwired-pipelines ***44*** to the framework-services layer ***72***. Because each hardwired pipeline ***44*** is different and typically has different interface specifications, the communication shell ***74*** is typically adapted for each hardwired pipeline. Consequently, in this embodiment, one provides design adjustments to create a unique version of the communication shell ***74*** for each hardwired pipeline ***44***. The designer provides these design adjustments by writing a unique communication-shell template ***112*** for each hardwired pipeline. Of course the group of communication-shell templates $\boldsymbol{112_{1,1}}$ – $\boldsymbol{112_{1,n}}$ corresponds only to the version of the framework-services layer ***72*** that is defined by the template $\boldsymbol{110_1}$; consequently, if there are multiple versions of the framework-services layer ***72*** that are compatible with the platform m=1, then the library section $\boldsymbol{122_1}$ includes a respective group of n communication-shell templates ***112*** for each version of the framework-services layer.

[73] In addition, the library section $\boldsymbol{122_1}$ includes a configuration template $\boldsymbol{118_1}$, which defines configuration constants having designer-selectable values as discussed above in conjunction with the configuration template ***118*** of **FIG. 5.**

[74] Furthermore, each template within the library section $\boldsymbol{122_1}$ includes, or is associated with, a respective description $\boldsymbol{126_1}$ – $\boldsymbol{134_1}$. The descriptions $\boldsymbol{126_1}$ – $\boldsymbol{132_{1,n}}$ describe the operational and other parameters of the circuitry that the respective templates $\boldsymbol{101_1}$, $\boldsymbol{108_1}$, $\boldsymbol{110_1}$, and $\boldsymbol{112_{1,1}}$ – $\boldsymbol{112_{1,n}}$ define. Similarly, the description $\boldsymbol{134_1}$ describes the settable parameters in the configuration template $\boldsymbol{118_1}$, the values that these parameters can have, and the meanings of these values. The design tool discussed below in conjunction with **FIGS. 7 – 11** uses the descriptions $\boldsymbol{126_1}$ – $\boldsymbol{134_1}$ to design and simulate a circuit that includes a combination of the hardwired pipelines $\boldsymbol{44_1}$ – $\boldsymbol{44_n}$, which are respectively defined by the templates $\boldsymbol{114_1}$ – $\boldsymbol{114_n}$. Examples of parameters that the descriptions $\boldsymbol{126_1}$

– ***132***$_{1,n}$ may describe include the width of the data bus and the depths of buffers that the circuit defined by the corresponding template includes, the latency of the circuit, and the precision of the values received and generated by the circuit. Furthermore, an example of a settable parameter and the associated selectable values that the description ***134***$_1$ may describe is BUS-WIDTH, which represents the width of the interface between the communication interface ***80*** and the bus connector ***56*** (**FIG. 4**), and BUS_WIDTH=0 sets the bus width to thirty-two bits and BUS_WIDTH=1 sets the width to sixty-four bits.

[75] Each of the descriptions ***126***$_1$ – ***134***$_1$ may be embedded within the respective template ***101***$_1$, ***108***$_1$, ***110***$_1$, ***112***$_1$ – ***112***$_{1,n}$, and ***118***$_1$ to which it corresponds. For example, the description ***128***$_1$ may be embedded within the template ***108***$_1$ as extensible markup language (XML) tags or comments that are readable by both a human and the tool discussed below in conjunction with **FIGS. 7 – 11**.

[76] Alternatively, each description ***126***$_1$ – ***134***$_1$ may be disposed in a separate file that is linked to the template to which the description corresponds, and this file may be written in a language other than XML. For example, the description ***126***$_1$ may be disposed in a file that is linked to the top-level template ***101***$_1$.

[77] The section ***122***$_1$ of the library ***120*** also includes a description ***136***$_1$, which describes the parameters of the platform m=1. The design tool discussed below in conjunction with **FIGS. 7 – 11** may use the description ***136***$_1$ to determine which platforms the library ***120*** supports. Examples of parameters that the description ***136***$_1$ may describe include 1) for each interface, the message specification, which lists the transmitted variables and the constraints for those variables, and 2) a behavior specification and any behavior constraints. Messages that the host processor ***12*** (**FIG. 1**) sends to the pipeline units ***50*** (**FIG 2**) and that the pipeline units send among themselves are further discussed in previously incorporated U.S.

Patent Publication No. 2004/0181621. Examples of other parameters that the description ***136***$_1$ may describe include the size and resources (*e.g.*, the number of multipliers and the amount of available memory) of the PLIC ***60*** (**FIGS. 2 – 4**). Furthermore, the platform description ***136***$_1$ may be written in XML or in another language.

[78] Still referring to **FIG. 6**, the section ***124*** of the library ***120*** includes *n* hardwired-pipeline templates ***114***$_1$ – ***114***$_n$, which each define a respective hardwired pipeline ***44***$_1$ – ***44***$_n$ (**FIGS. 2 – 4**). As discussed above in conjunction with **FIG. 5**, because the templates ***114***$_1$ – ***114***$_n$ are platform independent (the corresponding communication-shell templates ***112***$_{m,1}$ – ***112***$_{m,n}$ define the specified interface to the interface-adapter and framework-services layers ***70*** and ***72*** of **FIGS. 3 – 4**), the library ***120*** stores only one template ***114*** for each hardwired pipeline ***44*** (**FIGS. 2 – 4**). That is, each hardwired pipeline ***44*** does not require a separate template ***114*** for each platform that the library ***120*** supports. As discussed above, an advantage of this top-down design is that one need only create a single template ***114*** to define a hardwired pipeline ***44***, not *m* templates.

[79] Furthermore, each hardwired-pipeline template ***114*** includes, or is associated with, a respective description ***138***$_1$ – ***138***$_n$, which describes the parameters of the hardwired-pipeline ***44*** that the template defines. Like the descriptions ***126***$_1$ – ***134***$_1$ discussed above, the design tool discussed below in conjunction with **FIGS. 7 – 11** uses the descriptions ***138*** to design and simulate a circuit that includes a combination of the hardwired pipelines ***44***$_1$ – ***44***$_n$, which are respectively defined by the templates ***114***$_1$ – ***114***$_n$. Examples of parameters that the descriptions ***138***$_1$ – ***138***$_n$ may describe include the type (*e.g.*, floating point or integer) and precision of the data that the corresponding hardwired pipeline ***44*** can receive and generate, and the latency of the pipeline. Also like the descriptions ***126***$_1$ – ***134***$_1$, each of the descriptions ***138***$_1$ – ***138***$_n$ may be embedded within the respective template ***114***$_1$ – ***114***$_n$ to which the description corresponds as, *e.g.*, XML tags, or

may be disposed in a separate file that is linked to the template to which the description corresponds.

[80] Referring again to the library section ***122***$_1$, this section also includes a description ***140*** of the one or more available pipeline accelerators ***14*** (**FIG. 1**) that support the platform m=1. More specifically, the description ***140*** describes the resources that each of the pipeline accelerators ***14*** includes. For example, the description ***140*** may indicate that one available accelerator ***14*** includes only one pipeline unit ***50*** (**FIG. 2**), while another available accelerator includes five pipeline units. The description ***140*** may be written in XML or in another language.

[81] Still referring to **FIG. 6**, alternate embodiments of the library ***120*** are contemplated. For example, instead of each template within each library section ***122***$_1$ – ***122***$_m$ being associated with a respective description ***126*** – ***134***, each library section ***122***$_1$ – ***122***$_m$ may include a single description that describes all of the templates within that library section. For example, this single description may be embedded within or linked to the top-level template ***101*** or the configuration template ***118***. Furthermore, although each library section ***122***$_1$ – ***122***$_m$ is described as including a respective communication-shell template ***112*** for each hardwired-pipeline template ***114*** in the library section ***124***, each section ***122*** may include fewer communication-shell templates, at least some of which are compatible with, and thus correspond to, more than one pipeline template ***114***. In an extreme, each library section ***122***$_1$ – ***122***$_m$ may include only a single communication-shell template ***112***, which is compatible with all of the hardwired-pipeline templates ***114*** in the library section ***124***. In addition, the library section ***124*** may include respective versions of each pipeline template ***114*** for each communication-shell template ***112*** in the library sections ***122***$_1$ – ***122***$_m$.

[82] **FIG. 7** is a block diagram of a circuit-design system ***150***, which includes a computer-based software tool ***152*** for designing a circuit using

templates from the library ***120*** of **FIG. 6** according to an embodiment of the invention. By using library templates, the tool ***152*** allows one to design a circuit that includes a combination of one or more previously designed and debugged hardware-interface layers ***62*** (**FIG. 2**) and hardwired pipelines ***44*** (**FIGS. 2 – 4**). Because another has already tested and debugged the one or more layers ***62*** and pipelines ***44***, the tool ***152*** may significantly decrease the time required for one to design such a combination circuit as compared to a conventional design progression. Furthermore, where one wants to design a circuit for executing an algorithm, the tool ***152*** allows him to define the circuit with an expression of conventional mathematical symbols, where the expression defines the algorithm; consequently, one having little or no experience in circuit design can use the tool to design a circuit for executing an algorithm.

[83] The system ***150*** includes a processor (not shown) for executing the software code that composes the tool ***152***. Consequently, in response to the code, the processor performs the functions that are attributed to the tool ***152*** in the discussion below. But for clarity of explanation, the tool ***152***, not the processor, is described as performing the actions.

[84] In addition to the processor, the system ***150*** includes an input device ***154***, a display device ***155***, and the library ***120*** of **FIG. 6**. The input device ***154***, which may include a keyboard and a mouse, allows one to provide to the tool ***152*** information that describes an algorithm and that describes a circuit for executing the algorithm. Such information may include an expression of mathematical symbols, circuit parameters (*e.g.*, buffer width, latency), operation exceptions (*e.g.*, a divide by zero), and the platform on which one wishes to instantiate the circuit. And as described below, the device ***155*** displays the input information and other information, and the library ***120*** includes the templates that the tool ***152*** uses to build the circuit and to generate a file that defines the circuit.

[85] The tool ***152*** includes a symbolic-math front end ***156***, an interpreter ***158***, a generator ***160*** for generating a file ***162*** that defines a circuit, and a simulator ***164***..

[86] The front end ***156*** receives from the input device ***154*** the mathematical expression that defines the algorithm that the circuit is to execute and other design information, and converts this information into a form that is readable by the interpreter ***158***. To allow one to define a circuit in terms of the mathematical expression that defines the algorithm that the circuit is to execute, in one embodiment the front end ***156*** includes a web browser that accepts XML with a schema for Math Markup Language (MathML). MathML is software standard that allows one to enter expressions using conventional mathematical symbols. The schema of MathML is a conventional plug in that imparts to a web browser this same ability, *i.e.*, the ability to enter expressions using mathematical symbols. Alternatively, the front end ***156*** may utilize another technique for allowing one to define a circuit using a mathematical expression. Examples of such another technique include the technique used by the conventional software mathematical-expression solver MathCAD. Furthermore, as discussed below, one may enter the identity of a platform or pipeline accelerator ***14*** (**FIG. 1**) on which he wants the circuit instantiated, and may enter test data with which the simulator ***164*** will simulate the operation of the circuit. Moreover, one may enter valid-range constraints for any variables within the entered mathematical expression and constraints on execution of the expression, and may specify the action(s) to be taken if the constraints are violated. For example, because $-1 \leq sin(x) \leq 1$ for all values of x, for an expression that includes $sin(x)$, one may enter this constraint, and specify that any data generated from a value of $sin(x)$ outside of this range is to be disregarded. Or, because division by zero of any x yields infinity, one may specify that data generated in response to a division by zero is to be disregarded. The front end ***156*** then converts all of the entered information

into a format, such as HDL, that is compatible with the interpreter ***158***. Moreover, as discussed above, the front end ***156*** may cause the device ***155*** to display the input information and other related information. For example, the front end ***156*** may cause the device ***155*** to display the mathematical expression that the designer enters to define the algorithm to be executed by the circuit.

[87] The interpreter ***158*** parses the information from the front end ***156*** and determines: 1) whether the library ***120*** includes templates ***114*** (**FIG. 6**) defining hardwired pipelines ***44*** (**FIGS. 2 – 4**) that, when combined, can execute the algorithm entered by the designer, and 2), if the answer to (1) is "yes," which, if any, available pipeline accelerators ***14*** (**FIG. 1**) described by the description ***140*** in the library ***120*** has sufficient resources to instantiate a circuit that can execute the algorithm. For example, suppose the algorithm includes the mathematical operation $\sqrt{v}$. If the library ***120*** does not include a template ***114*** (**FIG. 6**) defining a hardwired pipeline ***44*** (**FIGS. 2 – 4**) that calculates the square root of a value, then the interpreter ***158*** determines that the tool ***152*** cannot generate a file ***162*** that defines a circuit for executing the algorithm. Furthermore, suppose that the circuit for executing the algorithm requires the resources of at least five PLICs ***60*** (**FIGS. 2 – 4**). If the description ***140*** indicates that the available accelerators ***14*** each have only three pipeline units ***50*** (**FIG. 2**), and thus each have only three PLICs ***60***, then the interpreter ***158*** determines that even though the tool ***152*** may be able to generate a file ***162*** that defines a circuit for executing the algorithm, one cannot implement this circuit on an available accelerator. The interpreter ***158*** makes a similar determination if the designer indicates that he wants the algorithm executed by a circuit having a sixty-four-bit bus width, but the available platforms support only a thirty-two-bit bus width. In situations where the interpreter ***158*** determines that the tool ***152*** cannot generate a circuit for executing the desired algorithm or that one cannot implement the circuit on an existing platform

and/or accelerator ***14***, the interpreter ***158*** causes the device ***155*** to display an appropriate error message (*e.g.*, "no library template for instantiating "√*v*," "insufficient PLIC resources," "bus-width not supported"). Furthermore, where the designer identifies a platform or accelerator ***14*** on which he desires to instantiate the resulting circuit, the interpreter ***158*** determines whether the circuit can be instantiated on the identified platform or accelerator. But if the circuit cannot be so instantiated, the interpreter ***158*** may determine that the circuit can be instantiated on another platform or accelerator, and thus may so inform the designer with an appropriate message via the display device ***155***. This allows the designer the choice of instantiating the circuit on another platform or accelerator ***14***.

[88] If the interpreter ***158*** determines that the library ***120*** includes a sufficient number of hardwired-pipeline templates ***114*** (**FIG. 6**) to define a circuit that can execute the desired algorithm, and also determines that the circuit can be instantiated on an available platform and accelerator ***14*** (**FIG. 1**), then the interpreter provides to the file generator ***160*** the identities of the hardwired-pipeline templates ***114*** that correspond to portions of the algorithm.

[89] The file generator ***160*** combines the hardwired pipelines ***44*** (**FIGS. 2 – 4**) defined by the identified hardwired-pipeline templates ***114*** such that the combination forms a circuit that can execute the algorithm.

[90] The generator ***160*** then generates the file ***162***, which defines the circuit for executing the algorithm in terms of the hardwired pipelines ***44*** (**FIGS. 2 – 4**) and the hardware-interface layers ***62*** (**FIG. 2**) that compose the circuit, the PLIC(s) ***60*** (**FIGS. 2-3**) on which the pipelines are disposed, and the interconnections between the pipelines (if multiple pipelines on a PLIC) and/or between the PLICs (if the pipelines are disposed on more than one PLIC).

[91] Next, the host processor ***12*** (**FIG. 1**) can use the file ***162*** to instantiate on the pipeline accelerator ***14*** (**FIG. 1**) the defined circuit as

discussed in previously incorporated U.S. Patent App. Ser. No. (Attorney Docket No. 1934-25-3). Alternatively, also as discussed in U.S. Patent App. Ser. No. (Attorney Docket No. 1934-25-3), the host processor ***12*** may instantiate some or all portions of the defined circuit in software executed by the processing unit ***32***. Or, one can instantiate the circuit defined by the file ***162*** in another manner.

[92] The simulator ***164*** receives the file ***162*** from the generator ***160*** and receives from the front end ***154*** designer-entered test data, such as a test vector, designer-entered constraint data, and a designer-entered exception-handling protocol, and then simulates operation of the circuit defined by the file ***162***. The simulator ***164*** also gathers parameter information (*e.g.*, precision, latency) from the description files ***138*** (**FIG. 6**) that correspond to the hardwired-pipeline templates ***114*** that define the pipelines ***44*** that compose the circuit. The simulator ***164*** may retrieve this parameter information directly from the library ***120***, or the generator ***160*** may include this parameter information in the file ***162***.

[93] **FIG. 8** illustrates the parsing of a symbolic mathematical expression by the interpreter ***158*** according to an embodiment of the invention. In other words, the syntax of the design language is the same as that used by mathematicians for writing algebraic equations. The explanations that follow show how a symbolic mathematical expression is a sufficient syntax for defining the hardwired pipelines ***44*** from a simple set of circuit primitives.

[94] **FIG. 9** illustrates a table of hardwired-pipeline templates ***114***, which correspond to the hardwired pipelines ***44*** (**FIGS. 2 – 4**) that the interpreter ***158*** (**FIG. 7**) identifies for executing portions of the parsed algorithm (**FIG. 8**) according to an embodiment of the invention.

[95] Referring to **FIGS. 5 – 9**, the operation of the tool ***152*** is discussed according to an embodiment of the invention.

[96] Suppose that one wishes to design a circuit that solves for a value *y*, which equals a mathematical expression according to the following equation:

$$y = \sqrt{x^4 \cos(z) + z^3 \sin(x)} \quad (2)$$

Also suppose that *x*, *y*, and *z* are thirty-two-bit floating-point values.

[97] Using the input device ***154***, the designer enters equation (2) into the front end ***156*** of the tool ***152*** by entering the following sequence of mathematical symbols: "√", "x^4", "·", "cos(z)", "+", "z^3", "·", and "sin(x)". The designer also enters information specifying the input and output message specifications, for example indicating that *x*, *y*, and *z* are thirty-two-bit floating-point values. The designer may also enter information indicating desired operating parameters, such as the desired latency, in clock cycles, from inputs *x* and *z* to output *y*, and the desired types and precision of any intermediate values, such as *cos(z)* and *sin(x)*, generated during the calculation of *y*. Furthermore, the designer may enter information that identifies a desired platform or pipeline accelerator ***14*** (**FIG. 1**) on which he wants the circuit instantiated. Moreover, the designer may specify the accuracy of any mathematical approximations that the tool ***152*** may make. For example, if the tool ***152*** approximates *cos(z)* using a Taylor series expansion, then by specifying the accuracy of this approximation, the designer effectively specifies the number of terms needed in the expansion. Alternatively, the designer may directly specify the number of terms in the expansion. The implementation of a function as a Taylor series expansion is further described below in conjunction with **FIGS. 13-17**.

[98] The front end ***156*** converts these mathematical symbols and the other information into a format compatible with the interpreter ***158*** if this information is not already in a compatible format.

[99] Next, the interpreter ***158*** determines whether any of the hardwired-pipeline templates ***114*** in the library ***120*** defines a hardwired pipeline ***44*** that can solve for *y* in equation (2) within the specified behavior and operating parameters and that can be instantiated within the desired platform and on the desired pipeline accelerator ***14*** (**FIG. 1**).

[100] If the library ***120*** does include such a template ***114***, then the interpreter ***158*** informs the designer, via the display device ***155***, that a conventional FPGA synthesizing and routing tool can generate firmware for instantiating this hardwired pipeline ***44*** from the identified template ***114***, the corresponding communication-shell template ***112***, and the corresponding top-level template ***101***.

[101] If, however, the library ***120*** includes no template ***114*** that defines a hardwired pipeline ***44*** that can solve for *y* in equation (2), then the interpreter ***158*** parses the equation (2) into portions, and determines whether the library includes templates ***114*** that define hardwired pipelines ***44*** for executing these portions within the specified behavior, operating parameters, and platform and on the specified pipeline accelerator ***14*** (**FIG. 1**).

[102] To identify a circuit that can solve for *y* in equation (2) but that includes the fewest number of hardwired pipelines ***44***, the interpreter ***158*** parses the equation (2) according to a top-down parsing sequence as discussed below. Typically, this top-down parsing sequence corresponds to the known algebraic laws for the order of operations.

[103] First, the interpreter ***158*** parses the equation (2) into the following two portions: "$\sqrt{}$", which is portion ***170*** in **FIG. 8**, and "$x^4\cos(z) + z^3\sin(x)$", which is portion ***172***.

[104] If the interpreter ***158*** determines that the library ***120*** includes at least two hardwired-pipeline templates ***114*** that define hardwired pipelines ***44*** for respectively executing the portions ***170*** and ***172*** of equation (2), then

the interpreter passes the identity of these templates to the file generator ***160***.

[105] In this example, however, the interpreter ***158*** determines that although the library ***120*** includes a hardwired-pipeline template ***114*** that defines a pipeline ***44*** for executing the square-root operation ***170*** of equation (2), the library includes no hardwired-pipeline template that defines a pipeline for executing the portion ***172***.

[106] Next, the interpreter ***158*** parses the portion ***172*** of equation (2). Specifically, the interpreter ***158*** parses the portion ***172*** into the following three respective portions ***174***, ***176***, and ***178***: "$x^4cos(z)$", "+", and "$z^3sin(x)$".

[107] If the interpreter ***158*** determines that the library ***120*** includes at least three hardwired-pipeline templates ***114*** that define hardwired pipelines ***44*** for respectively executing the portions ***174***, ***176***, and ***178*** of equation (2), then the interpreter passes the identity of these templates to the file generator ***160***.

[108] In this example, however, the interpreter ***158*** determines that although the library ***120*** includes a hardwired-pipeline template ***114*** that defines a hardwired pipeline ***44*** for executing the summing operation ***176*** of equation (2), the library includes no templates ***114*** that define hardwired pipelines for executing the portions ***174*** or ***178***.

[109] Next, the interpreter ***158*** parses the portions ***174*** and ***178*** of equation (2). Specifically, the interpreter ***158*** parses the portion ***174*** into three portions ***180*** ("x^4"), ***182*** ("·"), and ***184*** ("*cos(z)*"), and parses the portion ***178*** into three portions ***186*** ("z^3"), ***188*** ("·"), and ***190*** ("*sin(x)*").

[110] If the interpreter ***158*** determines that the library ***120*** does not include hardwired-pipeline templates ***114*** that define hardwired pipelines ***44*** for respectively executing each of the portions ***180***, ***182***, ***184***, ***186***, ***188***, and ***190***, then the interpreter displays via the device ***155*** an error message indicating that the library does not support a circuit that can solve for *y* in

equation (2). In one embodiment of the invention, however, the library ***120*** includes hardwired-pipeline templates ***114*** that provide the primitive operations for multiplication and for raising variables to a power (*e.g.*, cubing a value by using two multipliers in sequence) for single- or double-precision floating-point data types, and for data-type conversion. Also in this embodiment, the tool ***152*** recognizes common factors, for example that x is a factor of x^3 if $\sin(x^3)$ was needed instead of the $\sin(x)$, and generates circuitry to provide these common factors from chained multipliers.

[111] In this example, however, the interpreter ***158*** determines that the library ***120*** includes hardwired-pipeline templates ***114*** that define hardwired pipelines ***44*** for respectively executing each portion ***180***, ***182***, ***184***, ***186***, ***188***, and ***190*** of equation (2).

[112] Then, the interpreter ***158*** provides to the file generator ***160*** the identities of all the hardwired-pipeline templates ***114*** that define the hardwired-pipelines ***44*** for executing the following eight portions of equation (1): ***170*** ("$\sqrt{}$"), ***176*** ("+"),***180*** ("x^4"), ***182*** ("·"), ***184*** ("*cos(z)*"), ***186*** ("z^3"), ***188*** ("·"), and ***190*** ("*sin(x)*").

[113] Referring to **FIGS. 6 – 10**, the file generator ***160*** generates a table ***192*** (**FIG. 9**) of the hardwired-pipeline templates ***114*** identified by the interpreter ***158***, and displays this table via the device ***155***. In a first column ***194***, the table ***192*** lists the portions ***170*** ("$\sqrt{}$"), ***176*** ("+"),***180*** ("x^4"), ***182*** ("·"), ***184*** ("*cos(z)*"), ***186*** ("z^3"), ***188*** ("·"), and ***190*** ("*sin(x)*") of equation (2). In a second column ***196***, the table ***192*** lists the hardwired-pipeline template or templates ***114*** that define a hardwired pipeline ***44*** for executing the respective portion of equation (2). And in a third column ***198***, the table ***192*** lists parameters, such as the latency (in units of cycles of the signal that clocks the defined pipeline ***44***) and the input and output precision, of the hardwired pipeline(s) ***44*** defined by the templates ***114*** in the second column ***196***. As shown in the table ***192***, in this example the seven

hardwired-pipeline templates ***144_1*** – ***114_7*** in column ***196*** define hardwired pipelines ***44_1*** – ***44_7*** for respectively executing the corresponding portions of equation (2) in column ***194***. There are only seven pipeline templates ***114_1*** – ***114_7*** for the eight portions of equation (2) because the template ***114_5*** defines a multiplier pipeline ***44_5*** that can execute both "·" portions ***182*** and ***188***. Furthermore, although we have labeled the pipeline templates as ***114_1*** – ***114_7***, it is not required that these templates be sequentially ordered within the library ***120***. Moreover, the library ***120***, and thus the table ***192***, may include multiple templates ***114*** that define respective pipelines for executing each of the eight portions ***170***, ***176***, ***180***, ***182***, ***184***, ***186***, ***188***, and ***190*** of equation (2).

[114] Next, using the table ***192***, the file generator ***160*** selects the pipelines ***44*** from which to build a circuit that solves for *y* in equation (2). The generator ***160*** selects these pipelines ***44*** based on the behavior(s), operating parameter(s), platform(s), and pipeline accelerator(s) ***14*** (**FIG. 1**) that the designer specified. For example, if the designer specified that x, *y*, and z are thirty-two-bit floating-point quantities, then the generator ***160*** selects pipelines ***44*** that operate on thirty-two-bit floating-point numbers. If the available pipelines ***44*** for a particular portion of the equation (2) do not meet all of the designer's specifications, then the generator ***160*** may use a default set of rules to select the best pipeline. For example, the rules may indicate that if there is no available pipeline ***44*** that meets the specified latency and precision requirements, then, with the designer's authorization, the generator ***160*** defaults to the pipeline having the specified precision and the latency closest to the specified latency. Otherwise a new pipeline ***44*** with the specified latency is placed in the library, or the designer can select another pipeline from the table ***192***. As an example of satisfying the latency requirements, two versions of an x^4 circuit may be represented by respective hardwired-pipeline templates ***114*** in the library ***120***: a pipelined version using two fully registered multipliers in a cascade, or an in-place

version using a single, fully registered multiplier, a one-bit counter, and a multiplexer. The pipelined version consumes roughly twice the circuit resources but accepts one input value every clock cycle. In contrast, the in-place version consumes fewer circuit resources but accepts a new input value only every other clock cycle.

[115] Then, the file generator ***160*** interconnects the selected hardwired pipelines ***44*** to form a circuit ***200*** (**FIG. 10**) that can solve for *y* in equation (2). The generator ***160*** also generates a schematic diagram of the circuit ***200*** for display via the device ***155***.

[116] To form the circuit ***200***, the file generator ***160*** first determines how the selected hardwired pipelines $44_1 - 44_7$ can "fit" into the resources of a specified accelerator ***14*** (**FIG. 1**) (or a default accelerator if the designer does not specify one). For example, the file generator ***160*** calculates the number of PLICs ***60*** (**FIG. 3**) needed to contain the eight instances of the pipelines $44_1 - 44_7$ (this includes two instances of the pipeline 44_5)

[117] In this example, the generator ***160*** determines that each PLIC ***60*** (**FIG. 3**) can hold only a respective one of the pipelines $44_1 - 44_7$; consequently, the generator ***160*** determines that eight pipeline units $50_1 - 50_8$ are needed to instantiate the circuit ***200***.

[118] Next, based on the platform that the designer specifies, the generator ***160*** "inserts" into each of the PLICs $60_1 - 60_8$ of the pipeline units $50_1 - 50_8$ a respective hardware-interface layer $62_1 - 62_8$. Assuming that the designer specifies platform m=1, the generator ***160*** generates the layers $62_1 - 62_8$ from the following templates in section 122_1 of the library ***120***: the interface-adapter-layer template 108_1, the framework-services-layer template 110_1, and the communication-shell templates $112_{1,1} - 112_{1,7}$, which respectively correspond to the pipeline templates $114_1 - 114_7$, and thus to the pipelines $44_1 - 44_7$. More specifically, the generator ***160*** generates the hardware-interface layer 62_1 from the interface-adapter-layer

template 108_1, the framework-services-layer template 110_1, and the communication-shell template $112_{1,1}$. Similarly, the generator **160** generates the hardware-interface layer 62_2 from the templates 108_1, 110_1, and $112_{1,2}$, the hardware-interface layer 62_3 from the templates 108_1, 110_1, and $112_{1,3}$, and so on. Furthermore, because the PLICs 60_5 and 60_6 both will include the multiplier pipeline 44_5, the generator **160** generates both of the hardware-interface layers 62_5 and 62_6 from the interface-adapter and framework-services templates 108_1 and 110_1 and from the communication-shell template $112_{1,5}$; consequently, the hardware-interface layers 62_5 and 62_6 are identical but are instantiated on respective PLICs 60_5 and 60_6. Moreover, the generator **160** generates the hardware-interface layer 62_7 from the templates 108_1, 110_1, and $112_{1,6}$, and the hardware-interface layer 62_8 from the templates 108_1, 110_1, and $112_{1,7}$.

[119] Then, the generator **160** "inserts" into each hardware-interface layer $62_1 - 62_8$ a respective hardwired pipeline $44_1 - 44_7$ (the generator **160** inserts the pipeline 44_5 into both of the hardware-interface layers 62_5 and 62_6, the pipeline 44_6 into the hardware-interface layer 62_7, and the pipeline 44_7 into the hardware-interface layer 62_8). More specifically, the generator **160** inserts the pipelines $44_1 - 44_7$ into the hardware-interface layers $62_1 - 62_8$ by respectively inserting the hardwired-pipeline templates $114_1 - 114_7$ into the communication-shell templates $112_{1,1} - 112_{1,7}$.

[120] Next, the generator **160** interconnects the pipeline units $50_1 - 50_8$ to form the circuit **200**, which generates the value *y* from equation (2) at its output (*i.e.*, the output of the pipeline unit 50_8).

[121] Referring to **FIG. 10**, the circuit **200** includes an input stage **206**, first and second intermediate stages **208** and **210**, and an output stage **212**, and operates as follows. The input stage **206** includes the hardwired pipelines $44_1 - 44_4$ and operates as follows. The pipeline 44_1 receives a stream of values *x* via an input portion of the hardware-interface layer 62_1 and generates, in a pipelined fashion, a corresponding stream of values

sin(x) via an output portion of the layer **62_1**. Likewise, the pipeline **40_2** receives a stream of values *z* via an input portion of the hardware-interface layer **62_2** and generates, in a pipelined fashion, a corresponding stream of values z^3 via an output portion of the layer **62_2**, the pipeline **44_3** receives the stream of values *x* via an input portion of the hardware-interface layer **62_3** and generates, in a pipelined fashion, a corresponding stream of values x^4 via an output portion of the layer **62_3**, and the pipeline **44_4** receives the stream of values *z* via an input portion of the hardware-interface layer **62_4** and generates, in a pipelined fashion, a corresponding stream of values *cos(z)* via an output portion of the layer **62_4**.

[122] The first intermediate stage **208** of the circuit **200** includes two instantiations of the pipelines **44_5** and operates as follows. The pipeline **44_5** in the PLIC **60_5** receives the streams of values *sin(x)* and z^3 from the input stage **206** via an input portion of the hardware-interface layer **62_5** and generates, in a pipelined fashion, a corresponding stream of values $z^3 sin(x)$ via an output portion of the layer **62_5**. Similarly, the pipeline **44_5** in the PLIC **60_6** receives the streams of values x^4 and *cos(z)* from the input stage **206** via an input portion of the hardware-interface layer **62_6** and generates, in a pipelined fashion, a corresponding stream of values $x^4 cos(z)$ via an output portion of the layer **62_6**.

[123] The second intermediate stage **210** of the circuit **200** includes the hardwired pipeline **44_6**, which receives the streams of values $z^3 sin(x)$ and $x^4 cos(z)$ from the first intermediate stage **208** via an input portion of the hardware-interface layer **62_7**, and generates, in a pipelined fashion, a corresponding stream of values $z^3 sin(x) + x^4 cos(z)$ via an output portion of the layer **62_7**.

[124] And the output stage **212** of the circuit **200** includes the hardwired pipeline **44_7**, which receives the stream of values $z^3 sin(x) + x^4 cos(z)$ from the second intermediate stage **210** via an input portion of the hardware-interface layer **62_8**, and generates, in a pipelined fashion, a

corresponding stream of values $y = \sqrt{z^3 \sin(x) + x^4 \cos(z)}$ via an output portion of the layer ***62$_8$***.

[125] Referring to **FIGS. 7, 9,** and **10**, the designer may choose to alter the circuit ***200*** via the input device ***154***.

[126] For example, the designer may swap out one or more of the pipelines ***44$_1$*** – ***44$_7$*** with one or more other pipelines from the table ***192***. Suppose the square-root pipeline ***44$_7$*** has a high precision but a relatively long latency per the default rules that the generator ***160*** follows as discussed above. If the table ***192*** includes another square-root pipeline having a shorter latency, then the designer may replace the pipeline ***44$_7$*** with the other square-root pipeline, for example by using the input device ***154*** to "drag" the other pipeline from the table into the schematic representation of the PLIC ***60$_8$***.

[127] In addition, the designer may swap out one or more of the hardwired pipelines ***44$_1$*** – ***44$_7$*** with a symbolically defined polynomial series (*i.e.,* a Taylor Series equivalent) that approximates one of the pipelined operations. Suppose the available square-root pipeline ***44$_7$*** has insufficient mathematical accuracy per the designers' specification and the default rules that the generator ***160*** follows as discussed above. If the designer then specifies a new square-root function as a series summation of related monomials, then the front end ***156***, interpreter ***158***, and file generator ***160*** concatenate a series of parameterized monomial circuit templates into a circuit that solves for square roots. In this way the designer replaces the default pipeline ***44$_7$*** with the higher-precision square-root circuit using symbolic design. This example illustrates the symbolic use of polynomials to define new mathematical functions as established by Taylor's Theorem. A more detailed example is discussed below in conjunction with **FIGS. 13-17**.

[128] The designer may also change the topology of the circuit ***200***. Suppose that according to the default rules discussed above, the generator ***160*** places each instantiation of the hardwired pipelines $44_1 - 44_7$ into a separate PLIC ***60***. But also suppose that each PLIC ***60*** has sufficient resources to hold multiple pipelines ***44***. Consequently, to reduce the number of pipeline units ***50*** that the circuit ***200*** occupies, the designer may, using the input device ***154***, move some of the pipelines ***44*** into the same PLIC. For example, the designer may move both instantiations of the multiplier pipeline 44_5 out of the PLICs 60_5 and 60_6 and into the PLIC 60_7 with the adder pipeline 44_6, thus reducing by two the number of PLICs that the circuit ***200*** occupies. The designer then manually interconnects the two instantiations of the pipeline 44_5 to the pipeline 44_6 within the PLIC 60_7, or may instruct the generator ***160*** to perform this interconnection. Although the library ***120*** may not include a communication-shell template ***112*** that defines a communication shell ***74*** for this combination of multiple pipelines 44_5 and 44_6, the designer or another may write such a template and debug the communication shell that the template defines without having to rewrite the interface-adapter-layer and framework-services templates 108_1 and 110_1 and, therefore, without having to re-debug the layers that these templates define. This rearranging of pipelines ***44*** within the PLICs ***60*** is also called "refactoring" the circuit ***200***.

[129] Moreover, the designer may decide to breakdown one or more of the pipelines 44_1 - 44_7 into multiple, less complex pipelines ***44***. For example, to equalize the latencies in the stage ***206*** of the circuit ***200***, the designer may decide to breakdown the x^4 pipeline 44_3 into two x^2 pipelines (not shown) and a multiplier pipeline 44_5. Or, the designer may decide to replace the *sin(x)* pipeline 44_1 with a combination of pipelines (not shown) that represents *sin(x)* in a series-expansion form (*e.g.* Taylor series, MacLaurin series).

[130] Referring to **FIGS. 7** and **10**, after the designer has made any desired changes to the circuit ***200***, the generator ***160*** generates the file ***162***, which describes the circuit in terms of the pipeline units ***50***, the PLICs ***60***, the library templates that compose the circuit, and the interconnections between the pipeline units. Specifically, assuming that the designer has not modified the circuit ***200*** from the layout shown in **FIG. 10**, the file ***162*** indicates that the circuit is designed for instantiation on eight pipeline units 50_1 - 50_8 of a pipeline accelerator ***14*** (**FIG. 1**) that is compatible with platform m=1. The file ***162*** also identifies the eight PLICs $60_1 - 60_8$ on the eight pipeline units $50_1 - 50_8$, and for each PLIC, identifies the templates in the library ***120*** that define the circuitry to be instantiated on the PLIC. For example, referring to **FIGS. 6** and **10**, the file ***162*** indicates that the combination of the following templates in the library ***120*** defines the circuitry to be instantiated on the PLIC 60_1: 101_1, 108_1, 110_1, $112_{1,1}$, 114_1, and 116_1. Furthermore, the file ***162*** includes the values of all constants defined in the configuration template 118_1. The file ***162*** may also include one or more of the descriptions ***128 – 134*** and ***138*** corresponding to these templates, or portions of these descriptions. Moreover, the file ***162*** defines the interconnections between the PLICs $60_1 - 60_8$ and the message specifications for these interconnections The file ***162*** also defines any designer-specified range constraints for generated values, exceptions, and exception-handline routines. The generator ***160*** may write the file ***162*** in XML or in another language with XML tags so that both humans and other tools/machines can read the file. Alternatively, the generator ***160*** may write the file ***162*** in a language other than XML and without XML tags.

[131] Referring to **FIGS. 6, 7, 9**, and **10**, the designer may instruct the simulator ***164***, via the input device ***154***, to simulate the circuit ***200*** using a conventional simulation algorithm. The simulator ***164*** uses the information in the file ***162*** and the test vectors provided by the designer to simulate the operation of the circuit ***200***. The simulator ***164*** first determines

the operating parameters of the hardware-interface layers $62_1 - 62_8$ and of the hardwired pipelines $44_1 - 44_7$ from the file ***162***, or by extracting this information directly from the description files 128_1, 130_1, $132_{1,1} - 132_{1,7}$, and $138_1 - 138_7$ in the library ***120***. As discussed above, these parameters include, *e.g.*, circuit latencies, and the precision (*e.g.*, thirty-two-bit integer, sixty-four-bit floating point) of the values that the pipelines $44_1 - 44_7$ receive and generate. For example, from the description files 128_1, 130_1, $132_{1,1}$, and 138_1, the simulator ***164*** determines the latency of the PLIC 60_1 from the time a value *x* enters the hardware-interface layer 62_1 until the time that the layer 62_1 provides *sin(x)* on an external pin (not shown) of the PLIC 60_1. The latency information in these description files may be estimated information, or may be actual information derived from an analysis of an instantiation of the pipeline 44_1 and the hardware-interface layer 62_1 on the PLIC 60_1. The simulator ***164*** then estimates the latencies and other operating parameters of the PLICs $60_2 - 60_8$, and simulates the operation of the circuit ***200*** to generate an output test stream of values *y* in response to input test streams of values *x* and *z*.

[132] **FIG. 11** is a schematic diagram of the circuit ***200*** of **FIG. 10** disposed on a single pipeline unit ***50*** and in a single PLIC ***60*** according to an embodiment of the invention.

[133] Referring to **FIGS. 6, 7, 9**, and **11**, the operation of the tool ***152*** is discussed according to another embodiment of the invention.

[134] Following the same steps described above in conjunction with the formation of the circuit ***200*** of **FIG. 10**, the generator ***160*** determines that all of the hardwired pipelines $44_1 - 44_7$ (the multiplier pipeline 44_5 is instantiated twice) can fit within a single PLIC ***60*** with the same topology shown in **FIG. 10**.

[135] Although the library ***120*** includes no communication-shell templates ***112*** for this combination of the hardwired pipelines $44_1 - 44_7$, for simulation purposes the tool ***152*** derives the operational parameters and

message specifications of the hardware-interface layer ***62*** from the description files ***128$_1$***, ***130$_1$***, ***132$_{1,1}$*** – ***132$_{1,4}$***, and ***132$_{1,7}$***. Because the PLIC ***60*** incorporates the interface-adapter layer ***70*** and framework-services layer ***72*** defined by the templates ***108$_1$*** and ***110$_1$***, the tool ***152*** estimates the input and output operational parameters, *e.g.*, input and output latencies, and the message specifications of the layers ***70*** and ***72*** directly from the description files ***128$_1$*** and ***130$_1$***. Then, referring to **FIGS. 10 – 11**, because the values *x* and *z* are input in parallel to the pipelines ***44$_1$*** – ***44$_4$***, the tool ***152*** derives the input operating parameters of the communication shell ***74*** of **FIG. 11** from the description files ***132$_1$*** – ***132$_{1,4}$***, which describe the communications shells for the pipelines ***44$_1$*** - ***44$_4$***. For example, if the operational parameters of these communication shells are similar, then the tool ***152*** may merely estimate that the input-side operational parameters for the shell ***74*** are the same as the parameters from one of the description files ***132$_{1,1}$*** – ***132$_{1,4}$***. Alternatively, the tool ***152*** may estimate that an intermediate data-type translation is needed for the input-side operational parameters of the communication shell ***74***, or that an averaging operation is needed for the input-side operational parameters of the communication shell, if the respective input-side parameters in the description files ***132$_{1,1}$*** – ***132$_{1,4}$*** do not match. Similarly, because the values *y* are output from the pipeline ***44$_7$***, the tool ***152*** derives the output operating parameters for the communication shell ***74*** from the description file ***132$_{1,7}$***, which describes the communication shell for the pipeline ***44$_7$***. For example, the tool ***152*** may estimate that the output-side operational parameters for the shell ***74*** are the same as the output-side parameters from the description file ***132$_{1,7}$***.

[136] Next, the generator ***160*** generates the file ***162***, which defines the circuit ***200*** of **FIG. 11**, and the simulator ***164*** simulates the circuit using the operational parameters calculated for the hardware-interface layer ***62*** by the generator ***160***.

[137] **FIG. 12** is a block diagram of a circuit ***220***, for which the tool ***152*** of **FIG. 7** generates a file ***162*** according to an embodiment of the invention where the circuit solves for a variable in an equation that includes constant coefficients. The circuit ***220*** is similar to the circuit ***200*** except that the hardwired pipelines 44_2 and 44_3 respectively generate ax^4 and bz^3 instead of x^4 and z^3, where a and b are constant coefficients.

[138] In this embodiment, the designer wants to design a circuit to solve for *y* in the following equation:

$$y = \sqrt{ax^4 \cos(z) + bz^3 \sin(x)} \quad (3)$$

The only differences between equation (3) and equation (2) is the presence of the constant coefficients *a* and *b*.

[139] Referring to **FIG. 10**, one way for the tool ***152*** to generate such a circuit is to modify the circuit ***200*** is to parse equation (3) into portions including "$a \cdot x^4$" and "$b \cdot z^3$", and to add two corresponding PLICs (not shown) on which are instantiated the multiplication pipeline 44_5: one such multiplier PLIC between the PLICs 60_2 and 60_5 and receiving as inputs z^3 and *b*, and the other such multiplier PLIC between the PLICs 60_3 and 60_6 and receiving as inputs x^4 and *a*.

[140] Although such a modified circuit ***200*** is contemplated to accommodate the constant coefficients *a* and *b*, this circuit would require two additional pipeline units ***50***.

[141] Referring to **FIGS. 7, 10,** and **12**, in this embodiment, however, the tool ***152*** generates the circuit ***220*** by replacing the pipelines 44_2 and 44_3 in the circuit ***200*** with pipelines 44_8 and 44_9, which respectively perform the operations bz^3 and ax^4. Of course this assumes that the section ***124*** of the

library ***120*** (**FIG. 6**) includes corresponding hardwired-pipeline templates ***114***$_8$ and ***114***$_9$.

[142] Referring to **FIGS. 7** and **12**, to set the values of the coefficients *a* and *b*, the designer may enter the values as part of equation (3), or may enter the values separately. Assume that the designer wants *a*=2.0 and *b*=3.5. According to the former entry method, he enters equation (3) as: "$y=\sqrt{2x^4\cos(z)+3.5z^3\sin(x)}$". And according to the latter entry method, he enters equation (3) as $y=\sqrt{ax^4\cos(z)+bz^3\sin(x)}$, and then enters "*a*=2.0, *b*=3.5."

[143] The generator ***160*** then generates the file ***162*** to include the entered values for the coefficients *a* and *b*. These values may contained within one or more XML tags or be present in some other form.

[144] In another variation, the values of a and b may be provided to the configuration managers ***88*** (**FIG. 3**) of the PLICs ***60***$_3$ and ***60***$_2$ as soft-configuration data. More specifically, a configuration manager (not shown and different from the configuration managers ***88***), which is described in previously incorporated U.S. Patent App. Ser. No. (Attorney Docket No. 1934-25-3, 1934-26-3, and 1934-36-3) and which is executed by the host processor ***12*** (**FIG. 1**), initializes the values of *a* and *b* by sending configuration messages for *a* and *b* to the pipeline units ***50***$_3$ and ***50***$_2$. The accelerator-configuration registry ***40*** (**FIG. 1**) may store *a* and *b* as XML files to initialize the configuration messages created and sent by the configuration manager executed by the host processor ***12***.

[145] Still referring to **FIGS. 7** and **12**, the tool ***152*** can use similar techniques to set the values of constant coefficients for other types of circuit portions such as filters, Fast Fourier Transformers (FFTs), and Inverse Fast Fourier Transformers (IFFTs).

[146] Referring to **FIGS. 7 – 12**, other embodiments of the tool ***152*** and its operation are contemplated.

[147] For example, one or more of the functions of the tool ***152*** may be performed by a functional block (*e.g.*, front end ***156***, interpreter ***158***) other than the block to which the function is attributed in the above discussion.

[148] Furthermore, the tool ***152*** may be described using more or fewer functional blocks. In addition, although the tool ***152*** is described as either fitting the eight instantiations of the hardwired pipelines 44_1 - 44_7 in eight PLICs 60_1 - 60_8 (**FIGS. 10** and **12**) or in a single PLIC ***60*** (**FIG. 11**), the tool ***152*** may fit these pipelines in more than one but fewer than eight PLICs, depending on the resources available on each PLIC.

[149] Moreover, although described as allowing a designer to define a circuit using conventional mathematical symbols, alternate embodiments of the front end ***156*** of the tool ***152*** may lack this ability, or may allow one to define a circuit using other formats or languages such as C++ or VHDL.

[150] Furthermore, although the tool ***152*** is described as allowing one to design a circuit for instantiation on a PLIC, the tool ***152*** may also allow one to design a circuit for instantiation on an ASIC.

[151] In addition, although the tool ***152*** is described as generating a file ***162*** that defines an algorithm-implementing circuit, such as the circuit ***200*** (**FIG. 11**), for instantiation on a specific pipeline accelerator ***14*** (**FIG.14**) or on a pipeline accelerator that is compatible with a specific platform, the tool may generate, in addition to or instead of the file ***162***, a file (not shown) that more generally defines the algorithm. Such a file may include algorithm-definition data that is sometimes called "meta-data," and may allow the host processor ***12*** (**FIG. 1**) to implement the algorithm in any manner (*e.g.*, hardwired pipeline(s), software, a combination of both pipeline(s) and software) supported by the peer vector machine ***10*** (**FIG. 1**). Typically, meta-data describes something, such as an algorithm or another file, but is not executable. For example, the information in the description files ***126-134*** (**FIG. 6**) may include meta-data. But a processor, such as the

host processor ***12***, may be able to generate executable code from meta-data. Consequently, a meta-data file that defines an algorithm may allow the host processor ***12*** to configure the peer vector machine ***10*** for implementing the algorithm even where the machine does not support the implementation(s) specified by the file ***162***. Such configuring of the peer vector machine ***10*** is described in U.S. Patent Application Ser. No. (Attorney Docket Nos. 1934-25-3, 1934-26-3, and 1934-36-3), which were previously incorporated by reference.

[152] Moreover, the tool ***152*** may generate, and the library ***120*** (**FIG. 6**) may store, one or more meta-data files (not shown) for describing the messages that carry data to/from the PLICs ***60*** (or software equivalents) of a circuit, such as the circuit ***200*** (**FIG. 10**). For example, if the data generated by the PLICs ***60*** is floating-point data, then a meta-data file specifies this. The file ***162*** (**FIG. 7**) incorporates or points to these meta-data files so that the host processor ***12*** (**FIG. 1**) can instantiate the message objects that generate such messages as discussed in previously incorporated U.S. Patent App. Ser. Nos. (Attorney Docket Nos. 1934-25-3, 1934-26-3, and 1934-36-3).

[153] Furthermore, the tool ***152*** may generate, and the library ***120*** (**FIG. 6**) may store, one or more meta-data files (not shown) for describing the exceptions that the PLICs ***60*** (or software equivalents) of a circuit, such as the circuit ***200*** (**FIG. 10**), generate. For example, if a PLIC ***60*** implements a divide-by-zero exception, then a meta-data file specifies this. The file ***162*** (**FIG. 7**) incorporates or points to these meta-data files so that the host processor ***12*** (**FIG. 1**) can instantiate corresponding exception handlers as discussed in previously incorporated U.S. Patent App. Ser. Nos. (Attorney Docket Nos. 1934-25-3, 1934-26-3, and 1934-36-3).

[154] In addition, the tool ***152*** may generate, and the library ***120*** (**FIG. 6**) may store, one or more meta-data files (not shown) for describing the PLICs ***60*** (or software equivalents) of a circuit, such as the circuit ***200***

(**FIG. 10**). For example, such a meta-data file may describe the mathematical operation performed by, and the input and output specifications of, circuitry to be instantiated on a corresponding PLIC (or a software equivalent of the circuitry). The file ***162*** (**FIG. 7**) incorporates or points to these meta-data files so that the host processor ***12*** (**FIG. 1**) can 1) determine which firmware files (or software equivalents) stored in the library ***120*** or in another library will respectively cause the PLICs (or the host processor ***12***) to instantiate the desired circuitry, or 2) generate one or more of these firmware files (or software equivalents) that are not otherwise available, as described in previously incorporated U.S. Patent App. Ser. Nos. (Attorney Docket Nos. 1934-25-3, 1934-26-3, and 1934-36-3).

[155] Moreover, the library ***120*** (**FIG. 6**) may store one or more of the files ***162*** (**FIG. 7**) that the tool ***152*** generates, so that a designer can incorporate previously designed circuits, such as the circuit ***200*** (**FIG. 10**), into a new larger and more complex circuit. The tool ***152*** may then generate a new file ***162*** that defines this new circuit.

[156] Referring to **FIGS. 13-17**, according to another embodiment of the invention, the tool ***152*** (**FIG. 7**) allows one to design a circuit for implementing virtually any complex function *f(x)* by expanding the function into an equivalent infinite series. Many functions, such as *f(x) = cos(x)* and $f(x) = e^x$, can be expanded into an infinite series, such as the Taylor series or the following MacLaurin series, which is a special case (a=0) of the Taylor series:

$$(3) \qquad f(x) = f(0) + \frac{f'(0)}{1!}x + \frac{f''(0)}{2!}x^2 + \cdots + \frac{f^n(0)}{n!}x^n$$

Consequently, a combination of summing and multiplying hardwired pipelines ***44*** interconnected to generate $ax + bx^2 + cx^3 + \ldots + vx^n$ can implement any function *f(x)* that one can expand into a MacLaurin series, where the only differences in this combination of pipelines from function to

function are the values of the constant coefficients *a, b, c, . . ., v.* Therefore, if the tool ***152*** is programmed with, or otherwise has access to, the coefficients for a number of functions *f(x)*, then the tool can implement any of these functions as a series expansion. Furthermore, because the accuracy of the implementation of a function *f(x)* is proportional to the number of expansion terms calculated and summed together, the tool ***152*** may set the number of expansion terms that the interconnected pipelines ***44*** generate based on the level of accuracy for *f(x)* that the circuit designer (not shown) enters into the tool. Alternatively, a designer may directly enter a function *f(x)* into the front end ***156*** (**FIG. 7**) of the tool ***152*** in series-expansion form.

[157] **FIG. 13** is a block diagram of a circuit ***240*** that the tool ***152*** (**FIG. 7**) defines for implementing *f(x) = cos(x)* as a MacLaurin series according to an embodiment of the invention. For clarity, **FIG. 13** shows only the adders, multipliers, and delay blocks that compose the circuit ***240***, it being understood that the tool ***152*** may define the circuit for instantiation on one or more PLICs ***60*** using one or more hardwired pipelines ***44*** and one or more hardware-interface layers ***62*** (*e.g.*, **FIGS. 10** and **12**) per one of the techniques described above in conjunction with **FIGS. 7-12**. Furthermore, the circuit ***240*** may be part of a larger circuit (not shown) for implementing an algorithm having *cos(x)* as one of its portions.

[158] *F(x) = cos(x)* is represented by the following MacLaurin series:

$$\cos(x) = 1 - \frac{1}{2!}x^2 + \frac{1}{4!}x^4 - \frac{1}{6!}x^6 + \frac{1}{8!}x^8 \cdots \quad (4)$$

The circuit ***240*** includes a term-generating section ***242*** and a term-summing section ***244***. For clarity, only the parts of these sections that respectively generate and sum the first four power-of-x terms of the *cos(x)* series

expansion are shown, it being understood that any remaining portions of these sections for respectively generating and summing the fifth and higher power-of-x terms are similar.

[159] The term-generating section ***242*** includes a chain of multipliers ***246***$_1$ – ***246***$_p$ (only multipliers ***246***$_1$-***246***$_8$ are shown) and delay blocks ***248***$_1$-***248***$_q$ (only delay blocks ***248***$_1$-***248***$_3$ are shown) that generate the power-of-x terms of the *cos(x)* series expansion. The delay blocks ***248*** insure that the multipliers ***246*** only multiply powers of *x* from the same sample time.

[160] The term-summing section ***244*** includes two summing paths: a path ***250*** for positive numbers, and a path ***252*** for negative numbers. The path ***250*** includes a chain of adders ***254***$_1$-***254***$_r$ (only adders ***254***$_1$-***254***$_2$ are shown) and delay blocks ***256***$_1$-***256***$_s$ (only blocks ***256***$_1$ and ***256***$_2$ are shown). Similarly, the path ***252*** includes a chain of adders ***258***$_1$-***258***$_t$ (only adder ***258***$_1$ is shown) and delay blocks ***260***$_1$-***260***$_u$ (only blocks ***260***$_1$ and ***260***$_2$ are shown). A final adder ***262*** sums the cumulative positive and negative sums from the paths ***250*** and ***252*** to provide the value for *cos(x)*. Although the adder ***262*** is shown as summing the first five terms of the expansion (1 and the first four power-of-x terms), it is understood that the final adder ***262*** may be disposed further down the paths ***250*** and ***252*** if the circuit ***240*** generates additional terms of the *cos(x)* expansion. Where numbers being summed are floating-point numbers, exceptions, such as a mantissa-register underflow, may occur when a positive number is summed with a negative number that is almost equal to the positive number. But by providing separate summing paths ***250*** and ***252*** for positive and negative numbers, respectively, the circuit ***240*** limits the number of possible locations where such exceptions can occur to a single adder ***262***. Consequently, providing the separate paths ***250*** and ***252*** may significantly reduce the frequency of such floating-point exceptions, and thus may reduce the time that the peer-vector machine ***10*** (**FIG. 1**) consumes handling such exceptions and the size and complexity of the exception manager ***86*** (**FIG. 4**).

[161] Still referring to **FIG. 13**, the operation of the circuit ***240*** is discussed according to an embodiment of the invention. For purposes of explanation, it is assumed that each of the multipliers ***246***, adders ***254*** and ***258***, has a latency (i.e., delay) D of one clock cycle. For example, prior to a first clock edge, a value x is present at the inputs of the multiplier 246_1, and after the first clock edge, the value x2 is present at the output of the multiplier 246_1. It is understood, however, that the multipliers ***246*** and adders ***254*** and ***258*** may have different latencies and latencies other than one, and that the delays provided by the blocks ***248***, ***256***, and ***260*** may be adjusted accordingly.

[162] At a start time, a value x_1 is present at the input of the multiplier 246_1, where the subscript "1" denotes the time or position of x_1 relative to the other values of x.

[163] In response to a first clock edge, a value x_2 is present at the input of the multiplier 246_1, and x_1^2 is present at the output of this multiplier. For brevity, this example follows only the propagation of x_1, it being understood that the propagation of x_2 and subsequent values of x is similar but delayed relative to the propagation of x_1. Furthermore, for clarity, x_1 is hereinafter referred to "x" in this example.

[164] In response to a second clock edge, $-x^2/2!$ is present at the output of the multiplier 246_2, x^4 is present at the output of the multiplier 246_3, and x^2 is available at the output of the block 248_1.

[165] In response to a third clock edge, "1" is present at the output of the block 256_1, $x^4/4!$ is present at the output of the multiplier 246_4, x^6 is present at the output of the multiplier 246_5, and x^2 is available at the output of the block 248_2.

[166] In response to a fourth clock edge, $-x^6/6!$ is present at the output of the multiplier 246_6, x^8 is present at the output of the multiplier

246$_7$, x^2 is available at the output of the block ***248$_3$***, and "$1 + x^4/4!$" is available at the output of the summer ***254$_1$***.

[167] In response to a fifth clock edge, $x^8/8!$ is present at the output of the multiplier ***246$_8$***, "$1 + x^4/4!$" is available at the output of the block ***256$_2$***, and "$-x^2/2! - x^6/6!$" is available at the output of the adder ***258$_1$***.

[168] In response to a sixth clock edge, "$1 + x^4/4! + x^8/8!$" is available at the output of the adder ***254$_2$***, and "$-x^2/2! - x^6/6!$" is available at the output of the block ***260$_2$***.

[169] And in response to a seventh clock edge, "$\cos(x) = 1 - x^2/2! + x^4/4! - x^6/6! + x^8/8!$" ($\cos(x)$ approximated to the first four power-of-x terms of the MacLaurin series expansion) is available at the output of the adder ***262***. Therefore, in this example the latency of the circuit ***240*** (*i.e.*, the number of clock cycles from when x is available at the inputs of the multiplier ***246$_1$*** to when $\cos(x)$ is available at the output of the adder ***262***) is seven clock cycles. Furthermore, if the adder ***262*** summing a positive number and a negative floating-point number generates an exception, the exception manager ***86*** (**FIG. 4**) or the host processor ***12*** (**FIG. 1**) may handle this exception using a conventional floating-point-exception routine.

[170] Alternatively, if the circuit ***240*** calculates one or more higher power-of-x terms, then the adder ***262*** is located after (to the right in **FIG. 13**) the adder that sums the highest generated term to a preceding term, and the operation continues as above.

[171] Still referring to **FIG. 13**, alternate embodiments of the circuit ***240*** are contemplated. For example, the circuit ***240*** may include multipliers and adders to generate and sum the odd power-of-x terms (e.g., x, x3, x5) with the coefficients of these terms set to zero. Such an alternate circuit ***240*** is more flexible because it allows one to implement function expansions that include odd powers of x, but in this case would have a greater latency than seven clock cycles.

[172] **FIG. 14** is a block diagram of a circuit ***270*** that the tool ***152*** (**FIG. 7**) defines for implementing *f(x) = cos(x)* as a MacLaurin series according to another embodiment of the invention. The circuit ***270*** has a topology that reduces the number of delay blocks and the latency as compared to the circuit ***240*** of **FIG. 13**. Furthermore, like **FIG. 13**, **FIG. 14** shows only the adders, multipliers, and delay blocks that compose the circuit ***270***, it being understood that the tool ***152*** may define the circuit for instantiation on one or more PLICs ***60*** using one or more hardwired pipelines ***44*** and one or more hardware-interface layers ***62*** (*e.g.*, **FIGS. 10** and **12**) per one of the techniques described above in conjunction with **FIGS. 7-12**. Furthermore, like the circuit ***240***, the circuit ***270*** may be part of a larger circuit (not shown) for implementing an algorithm having *cos(x)* as one of its portions.

[173] The circuit ***270*** includes a term-generating section ***272*** and a term-summing section ***274***. For clarity, only the parts of these sections that respectively generate and sum the first four power-of-x terms of the *cos(x)* series expansion are shown, it being understood that any remaining portions of these sections for respectively generating and summing the fifth and higher power-of-x terms are similar.

[174] The term-generating section ***272*** includes a hierarchy of multipliers $276_1 - 276_p$ (only multipliers 276_1-276_8 are shown) and delay blocks 278_1-278_q (only delay blocks 278_1-278_2 are shown) that generate the power-of-x terms of the *cos(x)* series expansion. The delay blocks ***278*** insure that the multipliers ***276*** only multiply powers of *x* from the same sample time.

[175] The term-summing section ***274*** includes two summing paths: a path ***280*** for positive numbers, and a path ***282*** for negative numbers. The path ***280*** includes a chain of adders 284_1-284_r (only adders 284_1-284_2 are shown) and delay blocks 286_1-286_s (only block 286_1 is shown). Similarly, the path ***282*** includes a chain of adders 288_1-288_t (only adder 288_1 is

shown) and delay blocks ***290$_1$-290$_u$*** (only block ***290$_1$*** is shown). A final adder ***292*** sums the cumulative positive and negative sums from the paths ***280*** and ***282*** to provide the value for *cos(x)*. Although the adder ***292*** is shown as summing the first five terms of the expansion (1 and the first four power-of-x terms), it is understood that the final adder ***292*** may be disposed further down the paths ***280*** and ***282*** if the circuit ***270*** generates additional terms of the *cos(x)* expansion.

[176] Still referring to **FIG. 14**, the operation of the circuit ***240*** is discussed according to an embodiment of the invention. For purposes of explanation, it is assumed that each of the multipliers ***276***, adders ***284*** and ***288***, has a latency (i.e., delay) D of one clock cycle. It is understood, however, that the multipliers ***276*** and adders ***284*** and ***288*** may have different latencies and latencies other than one, and that the delays provided by the blocks ***278*** and ***288*** may be adjusted accordingly.

[177] At a start time, a value *x* is present at the input of the multiplier ***276$_1$***.

[178] In response to a first clock edge, x^2 is present at the output of the multiplier ***276$_1$***.

[179] In response to a second clock edge, x^4 is present at the output of the multiplier ***276$_2$***, and x^2 is available at the output of the block ***278$_1$***.

[180] In response to a third clock edge, "1" is present at the output of the block ***286$_1$***, $x^4/4!$ is present at the output of the multiplier ***276$_6$***, x^6 is present at the output of the multiplier ***276$_4$***, $-x^2/2!$ is available at the output of the multiplier ***276$_5$***, and x^8 is available at the output of the multiplier ***276$_3$***.

[181] In response to a fourth clock edge, $-x^6/6!$ is present at the output of the multiplier ***276$_7$***, $x^8/8!$ is present at the output of the multiplier ***276$_8$***, $-x^2/2!$ is available at the output of the block ***290$_1$***, and "$1 + x^4/4!$" is available at the output of the summer ***284$_1$***.

[182] In response to a fifth clock edge, "1 + $x^4/4!$ + $x^8/8!$" is available at the output of the adder ***284₂***, and "-$x^2/2!$ –$x^6/6!$" is available at the output of the adder ***288₁***.

[183] And in response to a sixth clock edge, "cos(x) = 1 – $x^2/2!$ + $x^4/4!$ – $x^6/6!$ + $x^8/8!$" (cos(x) approximated to the first four power-of-x terms of the MacLaurin series expansion) is available at the output of the adder ***292***. Therefore, in this example the latency of the circuit ***270*** is six clock cycles, which is one fewer clock cycle than the latency of the circuit ***240*** of **FIG. 13**. But as the number of the power-of-x terms increases beyond four, the gap between the latencies of the circuits ***270*** and ***240*** increases such that the circuit ***270*** provides an even greater improvement in the latency.

[184] Alternatively, if the circuit ***270*** calculates one or more higher power-of-x terms, then the adder ***292*** is located after (to the right in **FIG. 14**) the adder that sums the highest generated term to a preceding term, and the operation continues as above.

[185] Still referring to **FIG. 14**, alternate embodiments of the circuit ***270*** are contemplated. For example, the circuit ***270*** may include multipliers and adders to generate and sum the odd power-of-x terms (e.g., x, x3, x5) with the coefficients of these terms set to zero. Such an alternate circuit ***270*** may be more flexible because it allows one to implement function expansions that include odd powers of x without increasing the circuit's latency for a given highest power of x. That is, where the highest power of x generated by the circuit ***270*** is x^8, adding multipliers and adders to generate x^3, x^5, and x^7 would not increase the latency of the circuit ***270*** beyond six clock cycles. This is because the circuit ***270*** would generate the power-of-x terms in parallel, not serially like the circuit ***240*** of **FIG. 13**.

[186] **FIG. 15** is a block diagram of a power-of-x term generator ***300*** that the tool ***152*** (**FIG. 7**) defines to replace the power-of-x-term odd multipliers ***246₃***, ***246₅***, ***246₇***, . . . of the term-generating section ***242*** of **FIG. 13** and the power-of-x-term multipliers ***276₁***, ***276₂***, ***276₃***, ***276₄***, . . . of **FIG. 14**

according to an embodiment of the invention. Generally, the generator ***300*** includes fewer multipliers (here one) than the term-generating sections ***242*** and ***272*** (which each include eight multipliers), but may have a higher latency for a given number of generated power-of-x terms. Furthermore, like **FIGS. 13-14**, **FIG. 15** shows only the multipliers and other components that compose the term generator ***300***, it being understood that the tool ***152*** may define a circuit that includes the term generator for instantiation on one or more PLICs ***60*** using one or more hardwired pipelines ***44*** and one or more hardware-interface layers ***62*** (*e.g.*, **FIGS. 10** and **12**) per one of the techniques described above in conjunction with **FIGS. 7-12**.

[187] The term generator ***300*** includes a register ***302*** for storing x, a multiplier ***304***, a multiplexer ***306***, and term-storage registers $308_1 - 308_p$ (only registers $308_1 - 308_4$ are shown). For clarity, only the parts of the generator ***302*** that generates the first four power-of-x terms of the *cos(x)* series expansion are shown, it being understood that any remaining portions of the generator for generating the fifth and higher power-of-x terms are similar.

[188] Still referring to **FIG. 15**, the operation of the circuit ***300*** is discussed according to an embodiment of the invention. For purposes of explanation, it is assumed that each of the register ***302***, multiplier ***304***, and registers ***308*** has a respective latency (i.e., delay) of one clock cycle, and that the multiplexer ***306*** is not clocked, i.e., is asynchronous. It is understood, however, that the register ***302***, multiplier ***304***, and registers ***308*** may have different latencies and latencies other than one, that the multiplexer ***306*** may be clocked and have a latency of one or more clock cycles, and that the term-summing sections ***244*** and ***274*** of **FIGS. 13** and **14**, respectively, may be adjusted accordingly.

[189] At a start time, a value x is present at the input of the register ***302***.

[190] In response to a first clock edge, the current value of *x* is loaded into, and thus is present at the output of, the register ***302***, and is present at the output of the multiplexer ***306***, which couples its input ***312*** to its output. The register ***302*** is then disabled. Alternatively, the register ***302*** is not disabled but the value of x at the input of this register does not change.

[191] In response to a second clock edge, x^2 is present at the output of the multiplier ***304***, and the multiplexer changes state and couples its input ***314*** to its output such that x2 is also present at the output of the multiplexer ***306***.

[192] In response to a third clock edge, x^2 is loaded into, and thus is available at the output of, the register $\boldsymbol{310_1}$, and x^3 is available at the output of the multiplier ***304*** and at the output of the multiplexer ***306***.

[193] In response to a fourth clock edge, x^4 is available at the output of the multiplier ***304*** and at the output of the multiplexer ***306***.

[194] In response to a fifth clock edge, x^4 is loaded into, and thus is available at the output of, the register $\boldsymbol{310_2}$, and x^5 is available at the output of the multiplier ***304*** and at the output of the multiplexer ***306***.

[195] In response to a sixth clock edge, x^6 is available at the output of the multiplier ***304*** and at the output of the multiplexer ***306***.

[196] In response to a seventh clock edge, x^6 is loaded into, and thus is available at the output of, the register $\boldsymbol{310_3}$, and x^7 is available at the output of the multiplier ***304*** and at the output of the multiplexer ***306***.

[197] In response to an eighth clock edge, x^8 is available at the output of the multiplier ***304*** and at the output of the multiplexer ***306***.

[198] And in response to a ninth clock edge, x^8 is loaded into, and thus is available at the output of, the register $\boldsymbol{310_4}$, the next value of x is loaded into the register ***302***. But if the generator ***300*** generates powers of x

higher than x^8, the generator continues operating in the described manner before loading the next value of x into the register ***302***.

[199] After the generator ***300*** generates all of the specified powers of the current value of x, the register ***302***, multiplier ***304***, multiplexer ***306***, and registers ***310*** repeat the above procedure for each subsequent value of x.

[200] Alternative embodiments of the generator ***300*** are contemplated. For example, to generate the odd powers of x for a function other than cos(x), one can merely add additional registers ***310*** to store these values, because the multiplier ***304*** inherently generates these odd powers. Alternatively, the generator ***300*** may be modified to load x^2 into the register ***302*** so that the multiplier ***304*** thereafter generates only even powers of x. Moreover, one or more of the registers ***308*** may be eliminated, and the multiplexer ***306*** may feed the respective powers of x directly to the term multipliers, *e.g.*, the term multipliers ***246***$_2$, ***246***$_4$, ***246***$_6$, ***246***$_8$, . . . of **FIG. 13** and the term multipliers ***276***$_5$, ***276***$_6$, ***276***$_7$, ***276***$_8$, . . . of **FIG. 14**.

[201] **FIG. 16** is a block diagram of a circuit ***320*** that the tool ***152*** (**FIG. 7**) defines for implementing $f(x) = e^x$ as a MacLaurin series according to an embodiment of the invention. The circuit ***320*** is similar to the circuit ***240*** of **FIG. 13**, but because the odd power-of-x terms for the e^x expansion may be positive or negative, the circuit ***320*** also includes sign determiners (described below and in conjunction with **FIG. 17**) that respectively provide these odd-power-of-x terms to the proper path (positive or negative) of the term-summing section. For clarity, **FIG. 16** shows only the adders, multipliers, delay blocks, and sign determiners that compose the circuit ***320***, it being understood that the tool ***152*** may define the circuit for instantiation on one or more PLICs ***60*** using one or more hardwired pipelines ***44*** and one or more hardware-interface layers ***62*** (*e.g.*, **FIGS. 10** and **12**) per one of the techniques described above in conjunction with **FIGS. 7-12**.

Furthermore, the circuit ***320*** may be part of a larger circuit (not shown) for implementing an algorithm having e^x as one of its portions.

[202] $F(x) = e^x$ is represented by the following MacLaurin series:

$$(5) \qquad e^x = 1 + x + \frac{1}{2!}x^2 + \frac{1}{3!}x^3 + \frac{1}{4!}x^4 + \frac{1}{5!}x^5 \cdots$$

The circuit ***320*** includes a term-generating section ***322*** and a term-summing section ***324***, which includes positive- and negative-value summing paths ***326*** and ***328***. For clarity, only the parts of these sections that respectively generate and sum the first five power-of-x terms of the e^x series expansion are shown, it being understood that any remaining portions of these sections for respectively generating and summing the sixth and higher power-of-x terms are similar.

[203] The term-generating section ***322*** includes a chain of multipliers $\boldsymbol{330_1 - 330_p}$ (only multipliers $\boldsymbol{330_1}$-$\boldsymbol{330_8}$ are shown) and delay blocks $\boldsymbol{332_1}$-$\boldsymbol{332_q}$ (only delay blocks $\boldsymbol{332_1}$-$\boldsymbol{332_4}$ are shown) that generate the power-of-x terms of the ex series expansion. The section ***322*** also includes, for each odd-power-of-x term (*e.g.*, x, x^3, x^5, ...), a respective sign determiner $\boldsymbol{334_1 - 334_v}$ (only determiners $\boldsymbol{334_1 - 334_3}$ are shown) that directs positive values of the odd-power-of-x term to the positive summing path ***326*** of the term-summing section ***324***, and that directs negative values of the odd-power-of-x term to the negative summing path ***328***.

[204] The positive-value path ***326*** of the term-summing section ***324*** includes a chain of adders $\boldsymbol{336_1}$-$\boldsymbol{336_r}$ (only adders $\boldsymbol{336_1}$-$\boldsymbol{336_5}$ are shown) and delay blocks $\boldsymbol{338_1}$-$\boldsymbol{338_s}$ (only blocks $\boldsymbol{338_1 - 338_3}$ are shown). Similarly, the negative-value path ***328*** includes a chain of adders $\boldsymbol{340_1}$-$\boldsymbol{340_t}$ (only adders $\boldsymbol{340_1 - 340_2}$ are shown) and delay blocks $\boldsymbol{342_1}$-$\boldsymbol{342_u}$ (only blocks $\boldsymbol{342_1}$ - $\boldsymbol{342_2}$ are shown). A final adder ***344*** sums the cumulative positive and

negative sums from the paths ***326*** and ***328*** to provide the value for e^x. Although the final adder ***344*** is shown as summing the first six terms of the e^x expansion ("1" and the first five power-of-x terms), it is understood that the final adder may be disposed further down the paths ***326*** and ***328*** if the circuit ***320*** generates additional terms of the expansion.

[205] Still referring to **FIG. 16**, the operation of the circuit ***320*** is discussed according to an embodiment of the invention. For purposes of explanation, it is assumed that each of the multipliers ***330***, sign determiners ***334***, and adders ***336*** and ***340*** has a latency (i.e., delay) D of one clock cycle. It is understood, however, that the multipliers ***330***, sign determiners ***334***, and adders ***334*** and ***336*** may have different latencies and latencies other than one, and that the delays provided by the blocks ***332***, ***338***, and ***342*** may be adjusted accordingly.

[206] At a start time, a value *x* is present at both inputs of the multiplier 330_1, at the input of the delay block 332_1, and at the input of the sign determiner 334_1.

[207] In response to a first clock edge, x^2 is available at the output of the multiplier 330_1, x is available at the output of the delay block 332_1, and "1" is available at the output of the delay block 338_1. Furthermore, if x is positive, x and logic "0" are respectively available at the (+) and (-) outputs of the sign determiner 334_1; conversely, if x is negative, logic "0" and x are respectively available at the (+) and (-) outputs of the determiner 334_1.

[208] In response to a second clock edge, $x^2/2!$ is available at the output of the multiplier 330_2, x^3 is present at the output of the multiplier 330_3, and *x* is available at the output of the delay block 332_2. Furthermore, if x is positive, "1 + x" is available at the output of the adder 336_1; conversely, if x is negative, "1 + 0 = 1" is present at the output of the adder 336_1.

[209] In response to a third clock edge, $x^3/3!$ is available at the output of the multiplier $\mathbf{330_4}$, x^4 is available at the output of the multiplier $\mathbf{330_5}$, x is available at the output of the delay block $\mathbf{332_3}$, and "1 + x + $x^2/2!$" (x positive) or "1 + $x^2/2!$" (x negative) is available at the output of the adder $\mathbf{336_2}$.

[210] In response to a fourth clock edge, $x^4/4!$ is present at the output of the multiplier $\mathbf{330_6}$, x^5 is present at the output of the multiplier $\mathbf{330_7}$, x is available at the output of the block $\mathbf{332_4}$, and "1 + x+ $x^2/2!$" (x positive) or "1 + $x^2/2!$" (x negative) is available at the output of the delay block $\mathbf{338_2}$. Furthermore, if $x^3/3!$, and thus x, is positive, $x^3/3!$ and logic "0" are respectively present at the (+) and (-) outputs of the sign determiner $\mathbf{334_2}$; conversely, if $x^3/3!$, and thus x, is negative, logic "0" and $x^3/3!$ are respectively present at the (+) and (-) outputs of the determiner $\mathbf{334_2}$. Moreover, if x is negative, then x is available at the output of the delay block $\mathbf{342_1}$; conversely, if x is positive, then logic "0" is available at the output of the delay block $\mathbf{342_1}$.

[211] In response to a fifth clock edge, $x^5/5!$ is available at the output of the multiplier $\mathbf{330_8}$, "1 + x + $x^2/2!$ + $x^3/3!$" (x positive) or "1 + $x^2/2!$" (x negative) is available at the output of the adder $\mathbf{336_3}$, $x^4/4!$ is available at the output of the delay block $\mathbf{338_3}$, and "0" (x positive) or "-x - $x^3/3!$" (x negative) is available at the output of the adder $\mathbf{340_1}$.

[212] In response to a sixth clock edge, if $x^5/5!$, and thus x, is positive, $x^5/5!$ and logic "0" are respectively available at the (+) and (-) outputs of the sign determiner $\mathbf{334_3}$; conversely, if $x^5/5!$, and thus x, is negative, logic "0" and $x^5/5!$ are respectively available at the (+) and (-) outputs of the determiner $\mathbf{334_3}$. Furthermore, "1 + x + $x^2/2!$ + $x^3/3!$ + $x^4/4!$" (x positive) or "1 + $x^2/2!$ + $x^4/4!$" (x negative) is available at the output of the multiplier $\mathbf{336_4}$, and "0" (x positive) or "-x - $x^3/3!$" (x negative) is available at the output of the delay block $\mathbf{342_2}$.

[213] In response to a seventh clock edge, "1 + x + $x^2/2!$ + $x^3/3!$ + $x^4/4!$ + $x^5/5!$" (x positive) or "1 + $x^2/2!$ + $x^4/4!$" (x negative) is available at the output of the adder ***336***$_5$, and "0" (x positive) or "x - $x^3/3!$ - $x^5/4!$" (x negative) is available at the output of the adder ***340***$_2$.

[214] And in response to an eighth clock edge, "e^x = "1 + x + $x^2/2!$ + $x^3/3!$ + $x^4/4!$ + $x^5/5!$" (x positive) or "e^x = 1 - x + $x^2/2!$ - $x^3/3!$ + $x^4/4!$ - $x^5/5!$" (x negative) is available at the output of the adder ***344***.

[215] Therefore, in this example, the latency of the circuit ***320*** is eight. Furthermore, if the adder ***344***, while summing a positive number and a negative floating-point number, generates an exception, the exception manager ***86*** (**FIG. 4**) or the host processor ***12*** (**FIG. 1**) may handle this exception using a conventional floating-point-exception routine.

[216] Alternatively, if the circuit ***320*** calculates one or more power-of-x terms higher than the fifth power, then the adder ***344*** is located after (to the right in **FIG. 16**) the adder ***336*** or ***340*** that sums the highest generated term to a preceding term, and the operation continues as above.

[217] Still referring to **FIG. 16**, alternate embodiments of the circuit ***320*** are contemplated. For example, one may replace the term-generating section ***322*** with a section similar to the term-generating section ***272*** of **FIG. 14**, or may replace the chain of multipliers ***330*** with a power-of-x generator similar to the generator ***300*** of **FIG. 15**.

[218] **FIG. 17** is a block diagram of the sign determiner ***334***$_1$ of **FIG. 16** according to an embodiment of the invention, it being understood that the sign determiners ***334***$_2$ – ***334***$_v$ are similar.

[219] The sign determiner ***334***$_1$ includes an input node ***350***, a (-) output node ***352***, a (+) output node ***354***, a register ***356*** that stores a logic "0", and demultiplexers ***358*** and ***360***.

[220] The demultiplexer ***358*** includes a control node ***362*** coupled to receive a sign bit of the value at the input node ***350***, a (-) input node ***364***

coupled to the input node ***350***, a (+) input node ***366*** coupled to the register ***356***, and an output node ***368*** coupled to the (-) output node ***352***.

[221] Similarly, the demultiplexer ***360*** includes a control node ***370*** coupled to receive the sign bit of the value at the input node ***350***, a (-) input node ***372*** coupled to the register ***356***, a (+) input node ***374*** coupled to the input node ***350***, and an output node ***376*** coupled to the (+) output node ***354***.

[222] Still referring to **FIG. 17**, two operating modes of the sign determiner 334_1 are described according to an embodiment of the invention.

[223] In one operating mode, the sign determiner 334_1 receives at its input node ***350*** a positive (+) value *v*, which, therefore, includes a positive sign bit. This sign bit is typically the most-significant bit of *v*, although the sign bit may be any other bit of *v*. In response to the positive sign bit, the demultiplexer ***360*** couples *v* (including the sign bit) from its (+) input node ***374*** to its output node ***376***, and thus to the (+) output node ***354*** of the sign determiner 334_1. Furthermore, the demultiplexer ***358*** couples the logic "0" stored in the register ***356*** from the (+) input node ***366*** to the output node ***368***, and thus to the (-) output node ***352*** of the sign determiner 334_1.

[224] In the other operating mode, the sign determiner 334_1 receives at its input node ***350*** a negative (-) value *v*, which, therefore, includes a negative sign bit. In response to the negative sign bit, the demultiplexer ***358*** couples *v* (including the sign bit) from its (-) input node ***364*** to its output node ***368***, and thus to the (-) output node ***352*** of the sign determiner 334_1. Furthermore, the demultiplexer ***360*** couples the logic "0" stored in the register ***356*** from the (-) input node ***372*** to the output node ***376***, and thus to the (+) output node ***354*** of the sign determiner 334_1.

[225] Still referring to **FIG. 17**, alternative embodiments of the sign determiner 334_1 are contemplated. For example, one may replace the logic "0" register with a component, such as pull-down resistor, coupled to a logic "0" voltage level, such as ground.

[226] Referring to **FIGS. 1-17**, alternate embodiments of the peer vector machine ***10*** are contemplated. For example, some or all of the components of the peer vector machine ***10***, such as the host processor ***12*** (**FIG. 1**) and the pipeline units ***50*** (**FIG. 3**) of the pipeline accelerator ***14*** (**FIG. 1**), may be disposed on a single integrated circuit.

[227] The preceding discussion is presented to enable a person skilled in the art to make and use the invention. Various modifications to the embodiments will be readily apparent to those skilled in the art, and the generic principles herein may be applied to other embodiments and applications without departing from the spirit and scope of the present invention. Thus, the present invention is not intended to be limited to the embodiments shown, but is to be accorded the widest scope consistent with the principles and features disclosed herein.

WHAT IS CLAIMED IS:

1. A computer-based design tool, comprising:

a front end operable to receive symbols that define an algorithm;

an interpreter coupled to the front end and operable to parse the algorithm into respective algorithm portions; and

a generator coupled to the interpreter and operable to

identify a corresponding circuit template for each of the algorithm portions, each template defining a circuit for executing the respective algorithm portion, and

interconnecting the identified templates such that the interconnected templates define a circuit that is operable to execute the algorithm.

2. The design tool of claim 1 wherein the generator is operable to generate a file comprising:

a respective pointer to each of the identified templates within a template library; and

a list of the interconnections between the identified templates.

3. The design tool of claim 1 wherein the symbols comprise mathematical symbols.

4. The design tool of claim 1 wherein the interpreter is operable to parse the algorithm into respective algorithm portions that each correspond to a template in a library.

5. The design tool of claim 1 wherein the generator is operable to identify the corresponding templates by accessing a library that includes the identified templates.

6. The design tool of claim 1, further comprising a library coupled to the generator and operable to store the identified templates.

7. The design tool of claim 1, further comprising a simulator coupled to the generator and operable to simulate operation of the circuit by

determining a transfer function of the circuit defined by the interconnected templates.

8. The design tool of claim 1 wherein:

the front end is further operable to receive a desired operational characteristic of the circuit; and

the generator is further operable to identify the corresponding template for each of the algorithm portions such that the interconnection of identified templates defines the circuit having the desired operational characteristic.

9. The design tool of claim 8 wherein the desired operational characteristic comprises a latency of the circuit.

10. The design tool of claim 1 wherein:

the front end is further operable to receive an identity of a platform; and

the generator is further operable to,

identify a hardware-abstraction-layer template corresponding to the platform, and

interconnect the identified circuit templates to the identified layer template such that the interconnection of the templates defines the electronic circuit.

11. The tool of claim 1 wherein:

the front end is further operable to receive an identity of a platform; and

the generator is further operable to determine whether the circuit defined by the interconnection of the identified templates can be instantiated on the identified platform.

12. A computer-based design tool, comprising:

a front end operable to receive symbols that define an algorithm;

a generator coupled to the front end and operable to,

identify a template that defines a first electronic circuit that is operable to execute the algorithm,

identify a template that defines a hardware interface that is compatible with the first electronic circuit, and

interconnect the identified templates to define a resulting electronic circuit that includes the first circuit interconnected to the hardware interface.

13. A method, comprising:

parsing an algorithm into a combination of respective smaller algorithms;

identifying a corresponding template for each of the smaller algorithms, each template defining a respective circuit that is operable to execute the respective smaller algorithm; and

interconnecting the identified templates such that the interconnected templates define an electronic circuit that is operable to execute the algorithm.

14. The method of claim 13, further comprising:

generating a respective pointer to each of the identified templates within a library; and

generating a list of the interconnections between the identified templates.

15. The method of claim 13, further comprising:

receiving an expression of mathematical symbols that defines the algorithm; and

wherein parsing the algorithm comprises parsing the expression into groups of symbols that respectively define the smaller algorithms.

16. The method of claim 13 wherein identifying the corresponding templates comprises searching a library that includes the corresponding templates.

17. The method of claim 13, further comprising simulating the electronic circuit by:

determining a transfer function of the circuit from characteristics of the interconnected templates; and

determining a signal output from the circuit in response to a signal input to the circuit.

18. The method of claim 13 wherein identifying the corresponding templates comprises identifying the templates such that the interconnection of the templates represents the electronic circuit having a predetermined operational characteristic.

19. The method of claim 13, further comprising:

identifying an interface template that defines a hardware interface that is compatible with a predetermined platform on which the electronic circuit can be instantiated; and

wherein interconnecting the templates comprises interconnecting the circuit templates to the interface template such that the interconnection of the circuit and interface templates defines the electronic circuit.

20. The method of claim 13, further comprising determining whether the electronic circuit can be instantiated on a predetermined platform.

21. A method, comprising:

identifying a circuit template that defines a first electronic circuit that is operable to execute an algorithm;

identifying an interface template that defines a hardware interface that is compatible with the first electronic circuit; and

interconnecting the identified circuit and interface templates to generate a definition of a resulting electronic circuit that includes the first circuit interconnected to the hardware interface.

22. The method of claim 21, further comprising using the definition to instantiate the resulting electronic circuit on a programmable logic circuit.

23. The method of claim 21, further comprising using the definition to instantiate the resulting electronic circuit on a programmable logic circuit having signal pins such that the hardware interface is disposed between the pins and the first circuit.

24. The method of claim 21, further comprising simulating operation of the resulting electronic circuit based on information included in the circuit and interface templates.

25. The method of claim 21, further comprising simulating operation of the resulting electronic circuit based on information included in a description file that corresponds to the circuit and interface templates.

26. A computer-readable medium, that when executed by a processor, causes the processor to:

parse an algorithm into a combination of respective smaller algorithms;

identify a corresponding template for each of the smaller algorithms, each template defining a respective circuit that is operable to execute the respective smaller algorithm; and

interconnect the identified templates such that the interconnected templates define an electronic circuit that is operable to execute the algorithm.

27. A library, comprising:

one or more circuit templates that each define a respective circuit operable to execute a respective algorithm; and

an interface template that defines a hardware layer operable to interface one of the circuits to pins of a programmable logic circuit when the layer and the one circuit are instantiated on the programmable logic circuit.

28. The library of claim 27 wherein each circuit template includes extensible markup language that describes the respective algorithm.

29. The library of claim 27 wherein the interface template includes extensible markup language that describes the hardware layer.

30. The library of claim 27 wherein the programmable logic circuit comprises a field-programmable gate array.

31. The library of claim 27, further comprising a file that describes a platform with which the programmable logic circuit is compatible.

32. The library of claim 27 wherein the library comprises multiple circuit templates that define circuits that can be interconnected to for form a resulting circuit that can be instantiated one a programmable logic circuit to execute an algorithm.
